But it will be readily understood that the perfection of an apparatus whereby the power given out by these electrical generators may be stored up, kept for any period, and given out as desired, either in the form of light or motive power, would be an immense advantage, and would signalize a real advance in civilization. It would solve at once, and perfectly, the problem that is now engaging the attention of so many inventors; namely, that of introducing into our homes or places of business, a small, convenient power for sewing machines, elevators, etc., or for domestic lighting by electricity. It would place at our disposal a source of power in a compact, convenient, and portable form, that would be found serviceable in thousands of situations, and for thousands of uses. Whether or not the present forms of storage batteries, and particularly the system originally devised by Plante and improved by Faure and others, are capable of being so far perfected as to meet these expectations, the future alone can decide.

Mr. Edison, whose name and prestige as an electrical inventor entitle his opinions to much respect, as we have already stated in these columns, is reported to have lately said in substance the storage battery is a delusion—something that looked very well in theory, but could not be made to work in practice.

From what has already been accomplished in this field, however, we are firmly convinced that the day is near at hand when the problem of the storage of electricity will be solved in such a manner as to satisfactorily meet every requirement, if not with the systems now in vogue, then with others. Enough has already been accomplished to show that the theory of electrical storage is correct, and that the difficulties to be overcome in realizing the theory in practice are not insurmountable. Such being the case, with the incentive of the incalculable utility of the invention to urge them on, and the fact that the problem is being studied by the most accomplished and learned electricians of the day, we look forward to the solution of the problem as a matter of course. It is worthy of remark, also, in this connection, that Mr. Edison, if he is correctly reported, stands practically alone among electricians in his contemptuous opinion of the future of the storage battery.

At the present time, the storage battery has been so far perfected for practical uses that it is now employed for many purposes, where small power is required. In regard to its efficiency, some careful experiments were recently made at the Conservatoire des Arts et Metiers, in Paris, by a committee, of which M. Tresca was President. The battery experimented upon consisted of thirty-five cells, weighing about ninety-five pounds each, or, in all, say one and a half tons. It was charged by a Siemens machine, which absorbed the energy of one-horse power for thirty-five hours. Of this mechanical energy, thirty-four per cent was expended in useless work in the machine and battery during the operation of charging, and sixty-six per cent was stored as chemical energy in the battery. Of this stored energy, sixty per cent was recovered as electric energy. In other words, the actual work of one horse for thirty-five hours, after being stored in one and a half tons of battery, could be recovered to the extent of about fourteen hours' work of one horse, or the equivalent of the same in electric or other energy.

Although the above statement does not make a very high showing as regards efficiency, the committee making the experiments, remark in their report: "In many cases the loss would be fully counterbalanced by the advantage of having at hand, and entirely at one's disposal, so abundant a source of electricity." The main sources of loss are, first, local action between the negative lead plate and the peroxide of lead deposited upon it; and second, the resistance of the oxide and sulphate to the passage of the current, by reason of which energy is lost by being converted into useless heat in the battery, both at charging and discharging. By regulating the discharge of the battery so as to reduce this loss, and by giving seasons of repose, in which the battery recovers some of its deterioration, Messrs. Perry and Ayrton have succeeded in recovering eighty-two per cent of the energy put into one of these batteries.

Though the interest in the development of the storage battery centers chiefly in its application for lighting, it is very probable that its capability as a source of power in the small way, will prove to be most valuable, and that the time is not distant when power for sewing machines and for electric lighting in our houses will be delivered daily by express wagons.

The Great Red Spot on Jupiter.

Mr. G. D. Hiseox communicates an article to the *Scientific American*, in which, after alluding to the fact that the intensity of this spot seems to be vanishing after a duration of about two and a half years, he offers some speculation as to the philosophy of its occurrence, as follows:

The two periods of rotation of the spot are observed to vary about five and a half minutes; giving the rotation by the cloud spots as 9 h. 50 m. to 9 h. 50 m. 9 s., while the rotation by the great red spot is found to be 9 h. 55 m. 34 s.

The times given for rotation by observations upon different cloud spots also vary enough to give us, together with the varying contour of the cloud belt, strong evidence that what we see of the planet Jupiter is not the body of the planet itself, but rather a vast sea of cloud, possibly thousands of miles in depth, kept aloft by the intense heat of the body of the planet.

From the well known laws of circulation of gases, vapors, and cloud masses, as illustrated by the circulation of the atmosphere, together with the progress and direction of the great storms, cyclones, and tornadoes upon the earth, and as are beginning to be elucidated in the cyclone action of the sun spots, according to Faye's theory, which best meets the conditions deduced from spectroscopic observations; we cannot do otherwise than come to the conclusion that the solid body of Jupiter has never been seen—that our observations are only of the surface of vast envelope of cloud, that by its rapid rotation is constantly creating and keeping up an intercirculation, such as our trade winds and equatorial doldrums, upon a vast scale.

In this connection we have only to carry our minds back to the beginning of the Aztec age of our world, and to imagine the surface just erupting over and still red hot in zones, with our entire oceans hanging as a vast cloud above, and precipitating its dense vapors as rain upon the hot and hissing surface. It was then that the activity of natural forces were at their height. It was then that the upheaval of the intensely heated masses from below met the cloud bursts from above, and produced the same class of phenomena that has lately been observed, upon a vastly larger scale, upon the planet Jupiter.

If, in view of the density which has heretofore been given for Jupiter, we can reasonably accept an atmospheric or cloud depth of eight or ten thousand miles, the apparent great diameter of the red spot may be assumed as only the irradiation to, and illumination of the deep cloud stratum by an igneous mass, much smaller than the apparent size of the red spot, as we see it from the earth.

The size of the great spot, 26,000 by 8,000 miles, may be, for a planet 88,000 miles in diameter, only the illumination of a reasonable upheaval of the highly heated mass of the interior corresponding with the remains of such masses upon our earth.

The apparent retrograde motion I think is illusory, for I see no tenable reasoning to sustain the theory that has been advanced that it is a floating island, or crust floating upon a liquid surface. Nor does there appear any good reason for regarding it as of a periodical character, or bearing any relation to other periodical physical phenomena, as suggested by the Dearborn observer. But, on the other hand, an assertion in the report of the Dearborn observations, "that the apparent center of the red spot does not coincide with the true center, except when on the central meridian," goes far to explain the theory that the red spot, as seen by the telescope, is an area of the outer cloud stratum illuminated by an igneous mass upon the body of the planet. And also that its diurnal rotation should be fixed by the observed rotation of the red spot, instead of, as heretofore, by the rotation of the cloud spots.

THE ELECTROSCOPE.—The most astonishing claim yet made in behalf of electricity is that it has been proven possible to convey by its vibrations of light, so that it is practicable not only to speak to a distant friend, but to see him. According to the *Otago Times*, Dr. Guidrath, of Victoria, has invented an apparatus, called by him the electroscope, which accomplishes this. The paper in question says that a public test of this instrument was made in Melbourne in the presence of some forty scientific and public men. "Sitting in a dark room, they saw projected on a large disk of white burnished metal the racecourse at Flemington, with its myriad hosts of active beings. Each minute detail stood out with perfect fidelity to the original, and as they looked at the wonderful picture through binocular glasses, it was difficult to imagine that they were not actually on the course itself, and moving among those whose actions they could so completely scan."

PHOTOMICROGRAPHY.—Dr. G. M. Sternberg, U. S. A., delivered a lecture Tuesday evening before the San Francisco Microscopical Society, of which the Doctor is an honorary member. His subject, "Photomicrography," was illustrated with the camera, with the aid of which he exhibited views of the minute parasites which science has connected with diseases of man and animals, prodigiously magnified, showing distinctively every line and member of their infinitesimal organisms. The views were excellent, and were witnessed with profound interest by a large audience.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Stormont, April 24th, \$2,963; Ontario, 24th, \$11,000; Horn Silver, 24th, \$18,000; Ontario, 27th, \$6,530; Horn Silver, 27th, \$6,000; Yellow Jacket, 28th, \$9,728; Contention, 21st, \$22,624; Northern Belle, 26th, \$11,012; Bodie, 30th, \$14,730; Pinal Con., 11th to 22d, \$15,000; Standard, —, \$33,543; Navajo, 30th, \$14,100; Independence, 30th, \$6,000; Contention, 25th, \$11,850; Bodie Tunnel, 30th, \$2,063; Christy, 30th, \$4,190.

GRAVEL STRIKE.—A private dispatch from Downville states that the Bald mountain extension drift, and American hill hydraulic struck very rich gravel this week.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

LOYAL LEAD.—Amador Ledger, April 28: This quartz claim, adjoining the North Gover, near Drytown, and lately purchased by John Palmer and nine others, is to be prosecuted vigorously. The owners have moved the old Gover 10-stamp mill and placed it on the ground, and thoroughly repaired the same, and expect to get it started crushing some time this week. They are getting rock from the tunnel, which is 600 ft long, by working up on the ledge. There is plenty of rock to keep the 10 stamps going, and it is believed that it will pay well.

JACKSON.—After a period of idleness of several months, this quartz mine, otherwise known as the Ginochio claim, situated within the town limits of Jackson, resumed operations on Tuesday morning. The original bondholders, Messrs. Roberts, Adams and Peck, surrendered the bond in favor of a new company in San Francisco or Oakland, who are now proceeding with the work of development. The sum of \$2,000 was paid in liquidation of the old indebtedness, amounting to about \$5,000. A new bond will be given to the new company. W. L. Roberts is superintendent.

MAIMOTH.—The first clean-up of the mill of this famous bonanza mine, the property of W. A. Nevills, and situated in Middle Bar, was made Monday and Tuesday last. The run was for about 25 full days, most of the time, however, with only nine stamps, as one stamp was disabled, and had to be hung up. The run averaged 20 tons per day, or about 500 tons for the entire run. From all that we can learn from most trustworthy sources comestable, the yield far exceeded the most sanguine expectations. We are almost afraid to give an approximate of the output of gold, lest we should be put down as visionary. It is reported, however, that the clean-up realized somewhere between \$20,000 and \$30,000. Great chunks of gold were taken out of the batteries. One of the pieces is valued at \$140. In the mine, everything looks as well as ever, the streak of free gold continues about the same. All mining men who have seen this wonderful mine, unite in saying that nothing like it has been discovered in Amador county, and it bids fair to eclipse any mine now running in the State. The mill is idle for a few days, to enable some necessary repairing to be done.

MISCELLANEOUS.—I. N. Dewitt, Philbrook and four Austrians, are working on the first ledge struck in the Dewitt tunnel at Hunt's gulch. They have taken out 100 tons of rock, and are arranging to have it crushed at once. The Sinton Co., operating near Drytown, has secured the Maryland hoisting works, with the view of inaugurating sinking operations forthwith. The Canby Bros. had 60 tons of quartz from their mine near Volcano crushed this week at Down's mill. The yield, we are told, amounted to \$1300, or over \$21 per ton.

PLYMOUTH NOTES.—Cor. Amador Dispatch: Capt. Jenney is still prospecting on the Galileo and other ledges, with considerable success. We do hope that the Captain may be able to find something that will justify him in putting up extensive works as he is the best prospector that has ever been in this part of the country, or has ever been here, to our knowledge. The industry of the man is the thing that tells in this part of the country. The Vatican Co. have commenced sinking two new shafts, and are taking out large quantities of ore out of the old shaft, and the parties owning the mine say the prospects are much richer than ever before.

Calaveras.

WORK.—Mt. Echo, April 25: Work is progressing rapidly on Malone's Con. mine at Carson, and everything is apparently in a prosperous condition. A 40-stamp mill is in course of construction. The Gold Cliff is flourishing. Big clean-ups are being made. The new mill on the Confidence mine will be completed in a few weeks.

El Dorado.

GRAVEL MINING.—Mt. Democrat, April 28: The Cedar Springs mine, D. O. Cutter Supt., continues to pour forth its steady stream of the precious metal. On Saturday next a clean-up will be made after a five-weeks run, and there are good assurances that it will exceed by 30% to 50%, the result of the last clean-up, which was made after a four-weeks run and exceeded any former clean-up ever made in that mine, though for a long time it has been paying handsomely. Forty men are kept at work on this mine, and the shifts are so arranged that there is never any suspension of labor, even for an instant, not even to take meals, as the relief is set to work before the relieved men quit the mine. The gold turned out is of extra fine quality, commanding the highest price paid in the gold-dust market. Mr. Cutter is also superintendent of the Lyon and Kum Fa mines, which are under the same ownership as the Cedar Springs, and he is remembering the old Lyon tunnel for the purpose of working the Kum Fa ground through it, which latter, in the opinion of most old miners who are familiar with this section, is the most valuable gravel deposit in that vicinity. With the Blair gravel claim and the claims of Gignac and the E. D. W. & D. G. M. Co., at Texas Hill, and the Cedar and the Kum Fa in full blast, there is a promise of unprecedented returns from gravel mining in this neighborhood this fall.

BIG OPERATIONS AT THE SPRINGFIELD.—A contract has been let by Alvina Hayward to Prescott, Scott & Co., of the Union Iron Works, San Francisco, for machinery to be placed over a new shaft that is to be sunk on the Springfield mine, Mud Springs township, about 600 ft south of the present works. This machinery is to have a lifting power sufficient for workings 3000 ft in depth. It is to be supplied with a spur-gear hoist 12 ft in diameter and having a 12 inch face. It is to be run by water, with a Donnelly wheel from the Sutter Creek Pounding. A contract has been let for sinking the new shaft above referred to, a depth of 1000 ft. Blair brothers of this city have contracted to furnish 200,000 ft in lumber, 12 inches square, for timbering this shaft, a part of which will be delivered to-day. Masons have been down from this city during the week, laying the foundation for the new machinery.

ONION VALLEY MINING DISTRICT.—Georgetown Gazette, April 28: This district embraces a large

scope of country lying eastward from Gaddis creek, at an altitude of about 5,000 ft. The late rains have benefited this place considerably, and the mines are looming up at present with a fine supply of water. There are at present in active operation 13 mining claims, 6 being worked by the hydraulic process and 7 by sluices. The following creeks are at this time yielding gold in paying quantities: Onion, Bear, Sugar Pine, Bullion gulch, Ruby gulch, Grouse canyon (known as Finley's gulch,) Brush and Slab creeks. These creeks are from 1 to 5 miles long. There are also numerous other creeks, looking equally well, with an abundant supply of water, which are as yet unprospected. We have also numerous quartz lodes, but no quartz miners. There are also low lying channels here covered with lava, but no attempt has ever been made to get into them. The gold is generally found pretty deep in the bed-rock; hence mountain torrents must at some period have prevailed here. It may seem strange that our best prospectors and most successful miners here are young men who have done but little mining heretofore; they live by their claims winter and summer and improve every opportunity by getting them sluiced off during winter and spring, then clean up their bed-rock during the summer months. The "old timers" who come here generally returned without prospecting any at all, with the usual cry of "no gold."

Nevada.

A GOOD OUTLOOK.—Nevada Transcript, April 28: The Sherman Con., which was shut down a few days in order to make some required changes in the water pipes, again started up its new hoisting and pumping machinery, and expects to keep running regularly hereafter. Treviski & Laity have been awarded a contract for sinking the shaft 150 ft and they began their task last evening. Work at the Gold Flat Eureka, is temporarily suspended, pending the settlement of some matters in court. It is expected the mine will before long be in successful operation again. At the Mt. Auburn the 300, 450 and 600 levels are being steadily pushed northward to connect with the old Johnson shaft which was put down 90 ft in 1875 and is now to be reopened, sunk deeper, and made the main working shaft. The hoisting works are to be removed thence from their present location, as the incline through which the work is now being down is believed to be too far south to admit of the best part of the claim being worked to the greatest advantage. All the drifts show quartz of a good quality. It may be determined practical to remove the mill to a point in the canyon below, in order to give sufficient fall for introducing water as the motive power. In event of this change the mill and hoisting works will be connected by a tramway for the cheap and easy handling of ore. So little has been said in relation to the Mountaineer that few people besides those who are brought in contact with the company in a business way know of its existence. The mine is on Deer creek, about 600 yards this side of the Merrifield. The company have a 10-stamp mill, five of which are in operation night and day crushing rock from the mine. The ledge varies in size from two to four feet, and some of the specimen rock extracted is as rich as was ever taken out of any mine in the district. There are two ledges which are now coming together, and in a short time their true value will be known. The ledge that is now being worked is about two feet thick, and presents a very good appearance. If the property continues to look as favorable as now, the company will require hoisting works, which will be erected on the hill near the road. The property is owned mostly in San Jose, some stock being held in this city. At the Banner the 700 level is in 230 ft to the south and 260 to the north, work being prosecuted in both directions. A ledge shows in the south drift, and at times the ore found there is very good.

BUSY TIMES AT THE IDAHO.—Grass Valley Union, April 29: In and about the Idaho Works there is a scene of constant activity in the preparations being made for the introduction of water power. The line of 22-inch pipe has been laid from the reservoir down to a point about 1,000 ft from the works, and the water turned in, and is held at command by one of the gates. At the point the trial is being made of the different water wheels. Below this, toward the works, there are gangs of workmen, engaged in digging ditches and laying pipe, and before many days the whole line of pipe will be connected. The pipe now being laid down is all made at the works from 2-10th iron, the sheets being punched, rolled and riveted, and afterward immersed in a bath of coal tar. These pipes are all excellent pieces of workmanship, and made under the personal superintendence of Joseph S. Bonivert, who has no superior in the county as a boiler maker. As fast as the different joints are ready they are hauled by wagons to the point where needed and put in place. Millwrights are also at work framing the necessary timbers for the supports of the water wheels, of which five in number will be used for the several duties of hoisting, and running the batteries. Laborers are also engaged in digging out pits in which the wheels are to be set. A number of large wheels and other castings are on the ground, and the work generally is in quite a forward state, although the whole improvement is on so large a scale that it will take weeks yet to have everything in readiness to substitute water for steam in running all the machinery on the mine.

Placer.

FOREST HILL.—Cor. Placer Herald, April 26: As the mining industry is the most important hereabouts, that is what we first inquire into. The Excelsior Co. has been idle since the first of the month waiting the arrival of some of the owners, when arrangements will probably be made to sink a prospecting shaft on the Campbell ranch, then both shafts will be running at one time. At the Paragon, Messrs. Breech and Wheeler are driving ahead their bed-rock tunnel and with a few men are prospecting for the lead which was lost last summer. It seems strange that such a good paying channel should have stopped short all at once, but hopes are entertained that they will soon come on to it again. Messrs. Clark & Bequette are still working ahead with a large force of men. They are opening a very nice breast of gravel. In company with representatives of the Mayflower Co., I had the pleasure of going through the mine and saw some very nice looking gravel. The mine is being worked with a very large force of men. There are about 40 attending to the piping, etc., and no engaged sinking the new shaft. It is now about 150 ft deep. On Monday gravel was struck of a fair looking grade. It continues to improve in appearance the deeper they go, and is quite hard, which augurs well,

All interested in the mine feel very much elated. Over on Bushy the Adams Bros. are working their hydraulic claim with a crew of seven men. One day last week a 40-ounce piece of gold was picked up in Grinnell's diggings at Bath. Such pieces are rare and not often found now.

Plumas.
SOUTHERN EUREKA MINE.—*Greenville bulletin*, April 25: There is some talk of putting up more stamps at the mill of this mine; with what result may be expected when it is remembered that all the water that can now be got to the mill is not enough to supply the present capacity without being pumped back, and used over and over almost as long as it can be got to run at all. No other mine in the Greenville district has been less creditable to it than the Southern Eureka, and chiefly because it is impossible that it ever could or can be worked profitably with the mill in its present location. All who are interested in the district may well hope that the proposed addition to the mill may not be made, because if it is done the parties who invest the money with the expectation of getting it back through the mill will be disappointed, and further discredit will fall upon the district. That there is money to be made in the mine all competent judges who have examined it are agreed, but they are equally agreed that no money will ever be made with the mill where it now is.

GREEN MOUNTAIN MINE.—The tunnel has been in very hard ground during the past week or more. The rock is a gray quartzite, difficult to drill, and requiring more holes to be bored to advance a given distance than any hitherto found since the tunnel was started. Notwithstanding the character of the ground good progress has been made, and the ledge is likely to be made good that the ledge will be reached by the close of the month. The mills continue to run steadily.

GENESSEE MINE.—Mr. Eggleston, one of the parties interested is now at the mine, and last week engaged John Taylor as foreman. It is expected that the mill will be enlarged immediately and the mine worked upon a scale never attempted by the former owner.

Sierra.
ARASTRA.—*Mountain Messenger*, April 28: Jerome York has an arastra, in Slag canyon, running steadily, and confidently expects good pay, as he knows his quartz is rich. He says he knows more about an arastra than he did a month or two ago, for the simple reason that he bought and paid for the knowledge.

SIERRA CITY NOTES.—*Sierra County Tribune*, April 26: With the exception of Chinamen mining in the river, J. D. Newhouse was the only one we found digging for gold between Downieville and Loganville. Mr. Newhouse has a very pretty ranch and a nice residence. He also owns a gold mine. We found him, not hoeing in the garden, but manufacturing slickens out of the rich soil that composes the ranch. This is the kind of debris the Grangers are making such a howl about. Upon reaching Loganville we crossed the river to pay a visit to that famous quartz mine, the Marguerite. Famous, because we have been told that this little Sierra county mine has caused more excitement during the past year among the hells and bears of Boston than almost any other California mine. At the mine we found all bustle and activity. Everybody and everything seemed to be at work. We did not notice any idle hands around the premises. Supt. Shaw speaks well of our county and its bright future prospects. The 20-stamp mill is running regularly on good-paying ore. The condition of the mine is good. Since the Marguerite mine started up, somewhat over one year ago, Loganville has been gradually growing, until now it presents quite a town-like appearance. J. P. Deidesheimer, formerly a heavy owner in the Marguerite mine, was in Sierra City several days recently, on business connected with the Phoenix mine. We were informed that this mine would surely start up about the 1st of next month. It is estimated that there are a couple of hundred thousand dollars worth of ore already in sight at the mine. The Boston company, who will take hold of the property, proposes to push ahead work on an extensive scale this summer, in order to be well prepared for the coming winter season. The Phoenix ledge is located on the mountain side, similar to the Sierra Buttes ledge, and presents every advantage for working on equally as large a scale as that mine. Taking everything into consideration, Sierra City promises to develop into one of the most promising mining districts in the State.

Tuolumne.
POCKET.—*Tuolumne Independent*, April 24: Another large pocket was taken out at Tuttleton last week by a Cornish miner, near where the "Cardinal" strike was made, about 27 years ago. The miner was a stranger here, and went to work prospecting in the place that had been tramped over and worked around for years. He understood how this pocket "made," and got it—the same indications which led to the discovery having been for years exposed in an old shaft.

GEN. A. J. HATCH, of Nevada, is about to open the American tunnel, in conjunction with the Obar, in Table mountain, as soon as new track iron can be procured. The mine is paying far beyond expectation.

JOHNIE DAVIS, the enterprising miner, has a number of men at work on the Lamphier mine, near the old Confidence. They have a large vein showing well in ore. We have a number of specimens in our cabinet thickly set with free gold, taken from the mine a dozen years ago, when it was being prospected by Dave Baxter. Mr. Davis & Co. are making arrangements to erect a mill.

REOPENED.—*Union-Democrat*, April 28: The Divoll Bonanza mine has been reopened this week by Capt. Colby. As Colby is an experienced miner, and possessed of that confidential grit of which the majority of pocket miners are sadly deficient, we hope he will be successful. He has renovated the entire machinery connected with the mine, and intends running three shifts.

NEVADA.
Washoe District.

OPHIR.—*Enterprise*, April 28: On the 3100 level the joint Mexican east crosscut has been extended 28 ft. Are engaged in cleaning out and retimbering the old Central tunnel. The work of extracting ore from the croppings is continued.

UNION CON.—Have completed the winze chamber

in the joint Sierra Nevada east crosscut on the 2900 level. South drift No. 2 on the 2900 level has been extended 13 ft, and 91 tons and 1,600 pounds of ore extracted.

SURRA NEVADA.—The north lateral drift on the 2900 level has been extended 16 ft. The chamber for the winze in the end of the joint Union Con east crosscut on the 2900 level is completed. The north lateral drift on the 2900 has been extended four feet. During the past week there has been extracted from the north drift No. 2, on the 2900 level, 24 tons and 600 pounds of ore.

CROLLAR.—During the past week 56 ft were added to the length of crosscut No. 2, when further work at this point was discontinued. Since stopping this crosscut preparation has been made to start another, to be known as A, west from the main north lateral drift, at a point 92 ft north of crosscut No. 1. Everything is now ready, and the work of crosscutting will be started at once.

YELLOW JACKET.—The water in the mine remains at the same height, or stationary. At the Winters shaft we are extracting and shipping about 140 tons of ore daily. The north lateral drift on the Sagebrush level is now within 60 ft of our north line. The old ore stop is still on the east side of this drift. Work has been resumed in the north drift on the second level. On the 25th instant shipped three bars of bullion, valued at \$9,727.91.

Columbus District.

NORTHERN BELLE.—*True Fissure*, April 28: A crosscut has been started toward the footwall of the ledge found in the main winze, below the fifth shaft level. It begins at the east end of the drift from this winze, and has been extended 14 ft during the week. A crosscut from the fifth shaft level, at a point 200 ft from the shaft, has opened a body of black sulphurates, eight inches in width, which looks very promising. The crosscut is now in 28 ft, and will be continued until the footwall is reached. The southwest drift from the same level has advanced 10 ft, being now in a total distance of 56 ft. At this point a crosscut will be run in the same direction as the one just mentioned, and will enable a thorough prospecting of this section of the fifth shaft level. The stope from the fourth shaft level is yielding well and presents a promising outlook for the future. The stope from the first shaft level shows no diminution either in the quantity or quality of their ore production. Both mills are running steadily and doing good work. Five of the stamps of mill No. 2 are engaged in crushing custom ore. The hullion shipment was \$25,824.44 for the week ending April 26th, and amount to \$75,706.87 for the current month to the same date.

MOUNT DIABLO.—The stope above the connecting drift between winzes No. 1 and 2 shows a small streak of 570 ore. A wide ledge carrying 2½ ft of 570 ore has been developed in the stope from winze No. 2. The intermediate drift, below the third level and west of winze No. 1, shows a strong body of low grade ore, having lumps from which some \$45 ore is being stopped. The stope near the head of winze No. 2, on the third level, is yielding a quantity of \$75 quartz, and a little \$100 chloride is being taken from winze No. 4. The intermediate stope, between the second and third levels, and nearly above winze No. 1, is producing a small amount of \$200 chloride. A little 570 ore is being stopped from the east drift on the second level. A shipment of bullion, valued at \$5,444.40, was made on the 19th instant, and another of \$8,310.49 on the 23d.

Esmeralda District.

THE SILVER HILL MILL.—*Esmeralda Herald*, Capt. Morgan and Mex. Kilpatrick were in town yesterday, and visited the Silver Hill mill, at Gregory flat, for the purpose of making an estimate of the cost of fixing the mill for active service. Messrs. Ball & Groth propose to lease the mill to work the ore from the Centennial and other mines of this district, if the parties owning the mill will put it in good running order. H. Marden has the mill in charge, and, at his instance, Morgan & Kilpatrick were here to look at it and put in a bid for fixing it. The probability is the mill will be grinding away on Centennial ore in a few weeks.

Mount Cory District.

THE MINES.—*Cor. Bodie Free Press*, April 28: The Mount Cory mine employs but 15 men. They are not putting on any men, and I am credibly informed that it will be several months before they will increase the force at the mine, and I would advise all business and laboring men to steer clear of this camp for several months. There are at present more working and business men in the camp than can make a living. Men are leaving every day. The Mount Cory Co. has in contemplation the erection (at some future time) of reduction works, but no one can tell when or where, though most likely at Hawthorne, or within three or four miles of that place. The ore is very base and refractory. A great deal of the ore has been sent off to be tested at different places, and I suppose, of course, that process which will give the best results will be adopted. The Mount Cory mines are under the able management of Supt. A. G. McKenzie, of Comstock fame. Mac is slow and cautious, but he will be quick enough when he gets everything ready. Col. R. Webster, his efficient foreman, seconds Mac in the prosecution of the work. With Major Higgs as chief assayer, the mine is in good hands.

Safford District.

CHANGED HANDS.—*Eureka Sentinel*, April 28: It is understood that the Odondaga mine, Safford district, has recently passed into the hands of some heavy mining men, among whom J. T. Gilmer and George Hearst are chiefly mentioned. There is hardly any doubt that the mine has been bought by men who can, and will develop it for all it is worth. The Odondaga is probably the best prospect in Safford district, and the chances are it will show up and become a valuable mine. There are a number of other mines that promise well also. A revival of work on the Odondaga will be a good thing for Safford. It will bring life and hope into the camp again. The outlook is very fair in Safford district, and the chances are it will be a booming, prosperous camp before the summer is over.

Tuscarora District.

GRAND PRIZE.—*Times-Review*, April 26: West drift on the hanging wall ledge, 500 level, is in 44 ft; ledge small, and the ore is good. Have raised up 20 ft in it, and it improves in going up.

NAVAJO.—The 550-ft station is progressing very well. It will take three or four days to complete it.

The stopes are producing the usual grade and quantity of ore.

ARGENTIA.—Drift from winze is in 70 ft, and have commenced stoping. Repairing the mill as fast as possible.

ARIZONA.

CLIFTON NOTES.—*Tombstone Republican*, April 26: Bob Holmes, formerly special policeman here, has returned from Clifton, where he went some months ago. He pronounces the mines there as wonderful in extent and richness, and says it would be the best camp in Arizona but for the fact of the class of labor employed and wages paid. Of the 500 or 600 men at work not more than one third are white, the balance being Mexicans and Chinese, who, of course, receive the wages usually paid to those classes. The railroad is graded to the Gila river, distant from Lordsburg about 60 miles, leaving 45 miles to be completed.

RICH STRIKE IN VIZINA.—And now comes the Vizina with a rich strike, made in the lower levels some days since. The rock is manganese, and full of horn silver. Assays average \$900 per ton. The extent of the ore body is not yet developed, but the large amount of black wealth lying in the ore house indicates the strike a big one. The character of the rock is one not hitherto found in the Vizina.

PEACOCK DISTRICT.—*Mohave Miner*, April 22: There are now four men at work on the Infallible mine at Stockton. In blasting out a place to set timbers last week a fine streak of galena ore was discovered. James Mulligan, who has been working on the Crescent mine, in Peacock district, for the past eight or ten months, came in last Tuesday. He gives a glowing account of that mine, and tells us that all the ore taken from the mine has been shipped to the mill at Hackberry, and as soon as it has been milled, that Col. Thornlow, the superintendent of the mine, will resume work on a more extensive scale than heretofore. There are five men at work on Smith & Owens' copper mines near Cedar. It is expected that this fine property will soon change hands. The mill at Grass Springs is running on full time, and the new concentrating tables are doing splendid work and giving entire satisfaction. The work of transforming a 3x5 shaft into the Cupel mine, at Stockton, into a double-compartment shaft is progressing rapidly. There are a great many new prospectors in and about Stockton, and that city of Galena seems to be experiencing quite a boom. Wm. Freeborn came in from Cedar district last Tuesday, where he has been working for several months. He reports everything looking well in that flourishing district, and the miners are preparing to get out lots of ore ready for the 20-stamp mill to be erected on the Sandy. T. J. Christie and James Pemberton have been out to the Primrose mine in Peacock mountains, owned by them, and have brought in some fine samples of the ore for assay. They propose to do considerable work on this mine the coming summer. Erin Sherman is working on the Blue Boy mine, near the Lone Star, and has a big pile of ore on the dump. There is considerable excitement in Aubrey district over the new finds made by Eugene Desty, John Tillman and others, and a great many new claims have been taken up. Henry Ewing is getting ready a car-load of ore from some of his claims of Chloride, to be shipped to the Hubbs smelter at Albuquerque. Work is being vigorously prosecuted on the Keystone, and the mine is being rapidly put into proper shape for working.

PINAL MINES.—*Drill*, April 28: The Lone Will and By Chance mines, owned by W. Clark, have been worked for the last three years by arastra, and have produced ore in sufficient quantity and of a value to amply pay personal and mining expenses. Thirty-five assays taken from ore on the vein have produced an average of \$240 per ton. The ore is free milling ore with a preponderance of horn silver and native silver. Several shafts varying from five to 30 feet in depth, have been sunk. Mr. Clark has unbounded confidence in his mines and for the last three years has never been discouraged.

The News Letter is situated on the Josephine ledge, on which there are so many good locations. Mr. Chas. Brown, the proprietor of Congress Hall, Tucson, is the owner of this valuable mine. Mr. Brown has for years past been engaged in mining in our district and is the owner of some important mining locations. The work on the News Letter is under the charge of Mr. Thomas King. They are working in the main shaft, which is about 100 feet deep. They are about to drift northerly on the vein. They are working in porphyry and quartz. The vein at the bottom is three feet wide, and pay-streak one foot wide. Samples from the latter assay \$400. The ore is of the same character of chloride as is prevalent on the Josephine ledge, and this contains a considerable quantity of native silver.

COLORADO.

JAMESTOWN NOTES.—*Boulder News and Courier*, April 20: The Crocker mill has been running most of the time for several weeks past, and advertises to buy ores that run \$20 per ton or more. Its capacity is 10 tons per day. It has recently been treating ores from the December, Golden Age, Virginia, Mineral Point and other mines. Work is being pushed on the Virginia, and some fine ore from this mine has recently been treated by the Crocker Co. More work is now being done on the mines than ever before, and the results are more satisfactory. While the camp has been very quiet for a few days and business rather dull, we do not know of a single instance where men have invested anything in mines and have worked them but what they are satisfied with the result. Those that do the most grumbling are the ones that have done the least to help the camp. They came here to make a living off the honest laborers and have failed, and to all such chronic grumblers and dead-beats Jimtown is ready and willing to say good-bye. The shaft on the Argo has reached a depth of 62 ft, with ore about the same as has been encountered for 20 ft. The bonanza ledge, owned by the Crocker Co., and situated near the mill, is showing up well at a depth of 15 ft. On Monday the Crocker Co. bought from R. H. Clark 30 pounds of first-class ore that run \$3,447.15 per ton, mostly gold, and 226 pounds of second-class ore that run \$583 per ton. This ore was from the Franklin mine. The additions to and subtractions from the population of the camp about counter-balance each other. About as many are now coming out of the camp as are going in. The Inevitable, an old property that has recently fallen into the hands of Denver parties, is now considered one of the best properties in the camp. The present proprietors be-

gan taking out ore last week, and the first mill run of four sacks made \$218 per ton. Regular shipments of this ore will be made hereafter. An engine was bought this week and will be put up at once. Baker & Hagart are at work with a drill a short distance above the Buckhorn. Their progress is watched with much interest.

IDAHO.

GOLD.—*Idaho World*, April 24: Seventy pounds of analgam have been cleaned from the plates in the Golden Star mill. This analgam is worth \$4 or \$5 per ounce. It is expected the clean-up from the battery will be a big one. Over half of the gold, it is thought, remains in the battery. Sixty or 70 tons of ore have been crushed. The mine still looks splendid. Gold can be seen, without the aid of a glass, in almost every piece of ore picked up. Three men are at work in the stopes daytime and two at night, and are taking out rock faster than the mill can crush it.

MONTANA.

PHILIPSBURG NOTES.—*Cor. New Northwest*, April 24: The Algonquin mill is closed down and in the hands of the Sheriff. Mr. N. Connolly, long considered one of our most substantial merchants, became entangled in the mesh and has gone to the wall. Sheriff, Deputy Sheriff and Constable have been flying around hunting up and attaching everything, from a crowbar to a steam pump, belonging to any of the parties concerned; but, for once in the history of Philipsburg, a few of the workmen were sharp enough not to be caught out. They secured the bullion which was in the mill at the time of the burst up and removed it to some place unknown, where it remained until their money was paid. The Hope mill is still undergoing repairs under the jurisdiction of the old veteran mill man, Capt. Plasted, and will soon be heard thumping away again. Notwithstanding the deep snow and the inclemency of the weather, a good deal of work has been done upon the Granite Mountain. This is to Philipsburg, at present, "the land of promise," and, if it turns out a tenth as good as it prospers, it will do. Mr. Sim Shively reports continued success at the Willow creek quartz mines.

NEW MEXICO.

BULLION.—*Lake Valley Herald*, April 26: The Almbres M. Co. is going along as usual producing their full monthly amount of bullion.

The vein on the Dona Lu mine, at Bullard's peak, is four feet wide, opened 50 ft along the surface. The ore carries silver, copper, lead and iron. In one place a shaft has been sunk 40 ft, striking lead carbonates which assay 163 ounces in silver to the ton.

The Silver King mine is said to be a fine property. The ledge is 40 ft wide; average of ore, eight ounces on the surface. Two shafts are sunk, one on the north, the other on the south end, with 75 tons of ore on the dumps. The Silver Queen is the southern extension and shows mineral of similar description and value.

The Colossal, in the Burro mountains, six miles southwest of Black Hawk, is one of a group of nine mines. The main shaft is down 45 ft, assaying 350 ounces. A large quantity of ore is now on the dump, and work going rapidly forward. On the other claims of the group assessment work has been done. The average assays on the surface are 150 to 200 ounces in silver.

The Silver Bar, No. 2, mine, in the Mogollon mountains, is looking well. The company has on the dumps and in sight a large quantity of low-grade free-milling ore that averages \$20 per ton. The lead is from five to seven feet wide. One tunnel is driven in 176 ft. Next to the footwall of the vein runs a streak of copper-silver ore that averages in silver \$200 per ton. Assays have been made from this streak of mineral running as high as \$1,700 per ton. The President of the company is Chas. E. Slayback, of St. Louis. The company will soon erect reduction works. It is said there is ore enough now in sight to feed a 40-stamp mill for some time to come.

BRADLEY & RISQUE are the owners of a group of eight copper claims on the Middle Gila river, 30 miles from Silver City, from which a good wagon road runs direct to the mines. They are now in course of development.

ANOTHER rich strike has been made in the Bush mine, over beyond the South Percha, at the head of Trujillo creek in Grant county. This time it is at the bottom of a 110-ft shaft, and also in a drift run from the shaft at that depth. The ore is very rich in appearance, and will doubtless run up into the thousands when assayed. An open cut along the vein at the surface has also exposed at the bottom a foot streak of the same ore.

OREGON.

WASHINGTON DISTRICT.—*Cor. Bedrock Democrat*, April 25: The mines look well as far as prospected. Col. Barnes is still at work on the Daniel Boone, with good prospects. He has found some native silver in the ledge, which is two feet wide at a depth of 80 feet.

The Egan mine is 12 feet wide. They have run an open cut some six feet and it still holds its own, showing bromides and chlorides and native silver.

There are plenty of mines to be found in this country yet, as the country has never been prospected thoroughly. Almost every day men come in here and go away again cursing the country. We want men to take hold of our mines that have the money and energy to get up and open them. The prospectors here are all poor men, not able to open the mines as they should be; yet we have done well for the chance we have had. I do not think there has ever been a better field for capitalists on this coast than is presented here. We have silver, copper and iron in immense quantities, and every facility for working the same.

NOTES.—*Jacksonville Times*, April 28: John Barkdell and E. Rothen have commenced work at the big bar of Rogue river.

Brown, Feldt & Co., mining on Aithouse, have been doing well since water became plentiful. They picked up a fine nugget worth \$40 not long since.

Placer mining was a failure in most instances this season. Such dry weather was never experienced before, and the miners sincerely hope it never will be repeated.

The Sterling mine is being worked without interruption, though the ditch is not full as yet. A continuation of the weather of this week will melt the snow remaining in the mountains, when there will be plenty of water.

The Salmon Interest of the Northwest.

One of the great interests of the northwest is the canning of the magnificent salmon which frequent the waters of the Columbia and the other streams emptying into the Pacific. Salmon canning was begun on this coast by the Hume brothers and Andrew Hapgood, all of them having been engaged in salmon canning on the Kennebec river in Maine. They opened their first cannery opposite Sacramento city in March, 1864. In 1866, Wm. Hume, hearing something regarding the salmon prospects of the Columbia river, went up there and found that abundance of fish were being taken at Oak Point, Oregon, by Jotham Reed and his partner, two men from Maine, who had also been engaged in fishing on the Kennebec river, and who had for several years been fishing and salting salmon on the Columbia river. William Hume returned, and from his reports, the company decided to establish a cannery on the Columbia, and in the fall, George W. Hume went there and constructed the works at Eagle Cliff, Washington Territory. In 1867, their first season on the Columbia, the firm packed 4,000 cases of salmon, R. D. Hume and A. S. Hapgood making the cans. From this small beginning the business has advanced until there are now on the Columbia river alone not less than thirty-five canneries which produced in 1882 about 540,000 cases of canned salmon and including the other rivers from the Sacramento to the south of Alaska. On the north the product of canned salmon for 1882 was not far from 1,000,000 cases, with a value of about \$5,000,000.

In Mr. Hittell's "Commerce and Industries of the Pacific Coast" we find the following information concerning the canning interest of the Columbia: The salmon fishery of the Columbia gives employment in the season to 5,600 men, 3,100 Chinamen being employed in the canneries, while 2,500 whites take charge of the boats and nets. The cannery proprietors own 1,200 boats, and lease them with nets and all the necessary tools and supplies to the fishermen, a large proportion of whom are Scandinavians, Italians and Finns, who, as rent, must give one third of the catch, and must sell the other two thirds at a stipulated price. Each boat has two men, a captain and a helper. The former hires the latter, boards him, and gives him ten cents for every fish caught. The fishermen who own their boats and nets sell where they please, but usually receive the same price as is paid to the men using the cannery boats. It is expected that the captain of a boat will make at least \$100, and his helper \$70 a month for their labor. The average catch of a boat for a season may be 2,000 fish, worth \$1,200, equivalent to \$300 a month, of which \$100 is allowed for the use of the boat and net and other material. The price on the Columbia was sixty or sixty-two and a half cents a fish in 1881, the price having increased gradually since 1866 (and is still increasing.) In the canneries about 850 white men are employed as superintendents, clerks, foremen, etc., earning from \$50 to \$175 a month, averaging \$62. White men make the nets, cans, boats and cases, and have all the capital used in the business. The 3,100 Chinamen receive \$372,000 for their work of four months; the 850 white laborers in the canneries receive \$210,000; the 2,500 fishermen, \$850,000. The wages in the fishing season, and cost of fish paid by the canneries amount to \$1,433,000; and of this the 4,000 Chinamen get less than a third, while the 3,500 whites divide the other two thirds among themselves. The proprietors get \$2,750,000 for the product, leaving them \$1,316,400 above the cost of the fish and wages in the fishing season to pay other cannery expenses, interest on the investment and profits.

ENGINES FOR ELECTRIC LIGHTING.—Some idea of the progress which is being made in electric lighting may be formed from the following item: A. F. Upton, Boston, agent for the Armstrong & Sims engine, has received orders for twelve fifty-horse power engines of the Armstrong & Sims pattern, to be used for running electric lights in different places.

LIME FORMATION.—The hitherto much despised formation is now becoming all the rage with prospectors, and everybody is looking for rich deposits of metal in places where a few months ago they would have been ashamed to be found drunk. Thus does each section have peculiarities, and thus it is proved that mineral

change of sentiment will undoubtedly lead to many rich discoveries in all sections of the range, and while it cannot detract from the value of the many rich properties which are already known to exist on contacts of granite or porphyry, it can by directing attention in a new direction make the country more valuable.

Fig. 1.—THE MALE SALMON.

is where you find it and not entirely where theorists say it should be. In the Black range everywhere the bonanzas seem to be under a black lime capping, and in gash veins cutting through solid lime formation. The reason why these discoveries have not been made before is because most of the prospecting to date has been done on contacts of granite and porphyry,

DOES MINING PAY?—This is a conundrum that is being asked by half the papers of the Union. Does mining pay? Ask the thousands of men, who two years ago did not know what a bean was and who now feast upon beans three times every day of their lives. Ask them whether or not mining pays. Ask the other thousands of men, who two years ago, had

SALMON FISHING STATION ON THE COLUMBIA RIVER.

and lime has been abhorred and shunned. Lake valley and the Perchas were contradictions which puzzled the scientific and theoretical prospector and set him thinking, and the Polo-

never seen such a thing as a pair of canvas pants and who now wear canvas pants not only on Sundays, but every day of their lives—ask them whether or not mining pays. When you

Figs. 2 and 3.—MALE HEADS DURING THE SPAWNING SEASON.

Fig. 4.—FEMALE HEAD.

Fig. 5.—HUMPBACKED SALMON.

mas discoveries only were needed to revolutionize his ideas and set him to looking for his fortune in new quarters, until now it has come to pass that he will hardly glance at the ground to keep from stumbling when compelled to pass through a granite or porphyry region. This

go to head (and tail) quarters and ask for information as to the paying proclivities of mining as a business proposition, you get your answer in thunder tones from every cabin on the mountain side in which the bean pot is boiling and the slap-jack pan is sizzling, "It does!"

The Salmon.

The engravings given herewith well illustrate the salmon. Fig. 1 is a faithful representation of the male salmon in his normal condition as he comes in fat from the sea. He is then in his prime. The curve of the lip is a plain indication of the sex. When he strikes fresh water his taste for food leaves him and, eating nothing, he becomes thinner and thinner. The appearance of the head of the female is like that shown in Fig. 4, when the mouth is well shaped and the nose round and full. As the male fish proceeds up river his nose becomes hooked as shown in Fig. 2; and, later on, it gets even more hooked as Fig. 3 illustrates. There are several theories as to the cause of this gradual hooking of the nose. It used to be thought due to the increase of fighting propensities when the fish come into fresh water. That nature provided the hook nose then as a sort of weapon. Others thought it was to dig a sort of hole or hollow in the river bed where spawn might be deposited. Now, it is supposed to be used for breaking the tissues that hold the spawn in the female so that the spawn may be released and pass out. The fish is supposed to push against the female with the nose so as to break the tissue as stated.

Whatever the reasons, all male salmon, salmon trout, etc., get the hook nose. The nearer to the milting season the more pronounced the hook. When the fish return to the sea the nose again becomes rounded and the head assumes its normal shape.

Fig. 5 shows the head of a hump-backed salmon. In this, the hook nose is a very prominent feature, so much so that many believe it is the same species as the *Quinnat*, which we have just described, and that the fish assumes this shape, and returns to the shape shown in Fig. 1 after the spawning time. However, it is now conceded, we believe, that this is a distinct species. He has a very hooked nose and a regular rounded hump-back, being a homely fish, and not at all like the *Salmo Quinnat*, which is the variety we eat. The hump-back is found all along the coast up as far as Sitka, but is not very common.

Fig. 6 shows the appearance of one of the fishing stations along the river. Here are means for spreading and mending the nets, with houses for the fishermen.

What is called the fishing wheel is one of the innovations in the business, and is designed to supersede the fisherman. A large wheel is put up at one side of the river in a place where the fish run, and it is revolved by the current. There are scoops arranged, which catch the struggling fish as they try to go by, and these scoops throw the fish out where they are taken. These wheels catch the fish by thousands, much faster than the fishermen can do it. There is outcry against them, however, as it is said their use will deplete the supply of salmon.

A SIGNAL STATION AT MOUNT WHITNEY.—The Government has determined to establish a Signal Service station on the summit of Mount Whitney, and during the coming summer a detail from the engineer corps at the Presidio will be sent thither to make the necessary survey for that purpose. Mount Whitney is supposed to be the highest peak in the United States, having an altitude of 14,898 feet above the sea level. It is described as "the culmination point of an immense pile of granite, which is cut almost to the center by numerous steep, and often vertical canyons." It is situated on the west border of Inyo county, Cal., near the center of the Sierra Nevada, and about 325 miles southeast of San Francisco. The station will have an elevation more than double that of the station on Mount Washington, New Hampshire. At the latter station the winter gales attain a speed of 100 miles per hour. As the data on which storm predictions for this coast are obtained from stations north of San Francisco, that on Mount Whitney will not be as useful to this coast as the Mount Washington station is to the eastern seaboard. It will, however, serve for many important scientific purposes. The signal station at Point Barrow, the most northerly extremity of the western coast of North America, latitude 71° 24' N., is to be abandoned, and a vessel will be sent up next month to remove the party stationed there. There the winds in winter blow with a speed of over 100 miles per hour, and the mercury sinks below 50° below zero.

THE ENGINEER.

SCREW IN TUNNEL. The Lightning, one of the earliest torpedo boats supplied by Messrs. Thornycroft to the British service, has been lately subjected to a series of progressive speed trials at Portsmouth, under the superintendence of Chief Engineer Castle, of the Steam Reserve. The steering power of the craft, which is otherwise satisfactory, proved defective in consequence of the wide circle which she required to turn in. In order to surmount the difficulty the propeller has recently been encased in a tunnel; but while it was thought that the device might improve her handiness in going round, it was feared that it might detract from her speed. Trials were accordingly ordered to be made upon the measured mile in Stokes bay, for the purpose of comparison with the speed which she realized with the original propeller. Four runs were made at full speed, fourteen knots, twelve knots, and ten knots. When tested to the utmost, a mean speed of sixteen and one half knots was obtained, or about half a knot less than under the old conditions. The horse power developed, however, was also less, and as this is supposed to be due partly to the inferior character of the coal used, and partly to the fuel being forced over the bridge and so choking some of the boiler tubes, it is probable that further runs will be ordered. The steering in circling and going ahead was better than before, but in steering with the engine going astern the results were less satisfactory than with an open screw.

AMERICAN ENGINEERING. The story is told that, twenty years ago, one of our New England railroad companies did not dare to adopt the plans of its chief engineer for an iron bridge until they had been sent over to England and approved by experts there. Last year one of the leading English engineers designed a bridge in which there were two spans of 1,700 feet each, or 100 feet more than that of the East River bridge. This design has been most severely attacked by the Astronomer Royal, and a good deal of capital made out of it. The engineer, Mr. Baker, in replying to it says: "As a sample of foreign opinion, I would quote that of Mr. T. C. Clarke, the eminent American engineer and contractor, who has built more big bridges himself than are to be found in the whole of this country, and who has just completed a viaduct of 301 feet in height, by far the tallest in the world. Referring to the proposed bridge, he writes: 'If my opinion is of any value, I wish to say that a more thoroughly practical and well considered design I have never seen.' I need hardly say that the opinion of such a man has far more weight than that of an army of amateurs." This, as the *Railroad Gazette* says, is a very gratifying evidence that American engineering is growing in its reputation abroad.

THE HUDSON RIVER TUNNEL.—Work upon the New York side of this tunnel, which was suspended about six months since, has now been resumed. The water was pumped from the excavation, and it was found that the brick walls of the tunnel were not injured in the least. One of the engineers engaged in the work says: "We are making very satisfactory progress. Since the work was suspended the river bed at the outer end of the tunnel has become more solid. After we get about thirty feet farther we shall strike a loamy soil similar to that through which the tunnel on the other side of the river has been dug, and will be able to push the work much faster. We are now making progress at the rate of about two or three feet a day." The tunnels on the New Jersey side of the river have been kept free of water as far out as the air-lock in each tunnel. Work was also suspended at about the same time on the Jersey side, where it has not yet been resumed, but will soon be after Mr. Chas. G. Francklyn, the President of the company, returns from Europe.

THE TEJACATEPEC SHIP-RAILWAY.—Capt. James B. Eads has resigned his position in the Government River Commission, to devote his attention exclusively to his ship-railway project. It appears that complete arrangements have been made in England for the necessary capital to complete the work, and inside of five years the railway will be carrying ships weighing, with their cargoes, 5,000 gross tons from the Gulf to the Pacific and from the Pacific to the Gulf. The construction of this railway will shorten the distance between New Orleans and San Francisco by fully 2,200 miles—making a saving of 4,400 miles on the round trip.

THE PANAMA CANAL.—Unless Mr. Charles Lesseps, who has just been interviewed in New York, presents an unwarrantably rose-colored view of the situation, work on the Panama canal has been pushed forward with an energy and success of which the American public generally has but an inadequate idea. M. De Lesseps reports that the work is less difficult than had been expected, and he professes to be hopeful of its completion in five years' time. No less surprising is his statement that the company is in no want of funds.

THE CANADIAN PACIFIC RAILROAD is still progressing westward at a very rapid rate. On the 24th of April, two miles of track were laid, making 597 miles of continuing track westward from Lake Winnipeg.

USEFUL INFORMATION.

Cleaning Watches with Benzine.

A correspondent of the *Watchmaker and Metalworker* tells how he cleans watches with benzine. The method may be useful for other fine work. He says: I immerse the parts in benzine and dry in boxwood sawdust. This gives the gilding a fresh, new look which I have never been able to get by any other process. The movement must be entirely taken down. The dial screws may be screwed down tightly and left, but all parts mated with screws must be separated, so that there will be no places where the benzine can remain and not be at once absorbed by the sawdust.

I have a large alcohol cup, which I fill about half full of benzine, taking down my movement and putting the larger pieces in the fluid. The scape wheel, balance, and delicate parts I treat separately, that they may not be injured by contact with the heavier pieces. I then take the pieces one at a time, and tumble them into the sawdust. In a few seconds they will be dry, when I pick them out and lay them in a tray, using brass tweezers, which do not scratch. I treat all the parts in this way except the mainspring, when a slight use of the brush and clean chamois will remove all dust. Of course, the holes must be cleaned with a pointed peg, and I wipe out the oil sinks with chamois over the end of a blunt peg, but it is not often necessary to clean the pinions with a peg; they will come out of the sawdust bright and clean.

The mainspring must not be put into benzine unless you want it to break soon after. The fluid seems to remove the fine oily surface which a spring gets after working for a time, and which is very desirable to retain; so I clean my springs by wiping with soft tissue paper. If they are gummy I put on a little fresh oil to soften, and wipe off, being careful not to straighten out the spring.

SOLIDIFIED MILK, OIL, WHISKY, ETC.—In the market of Jokutok, the Siberian town, whose name has become so familiar to American readers through the story of the ill-fated *Jeanette*, it is said milk is sold by the block—frozen. Each block has a string or stick frozen into it for convenience in carrying.

We have already in these columns made mention of the solidification of oil, and now, in addition to these two substances, it is said that some ingenious chemist has succeeded in solidifying whisky, so that it may be carried about in casks in the waistcoat pocket and resorted to at any hour of the day or night. He must be a very ingenious fellow indeed, who has done anything one half so clever. In this country, at least, the essential element of whisky is alcohol, and alcohol has never been solidified. Even under the greatest pressure it only becomes a viscous fluid. From all that we have ever heard of American whisky, however, we think it very likely that its composition is so peculiar as to make its solidification quite possible, but the man who would carry it about in his waistcoat pocket, must indeed be an ardent opponent of total abstinence.

WHITE BRONZE.—Experiments are being made, according to the *Polytechnische Notizblatt*, in Paris with a new alloy having a white color yet containing no nickel. It is said to be very strong and malleable. It is made of copper and ferro-manganese, the proportions being varied according to the purpose to which the alloy is to be employed. An alloy of forty parts of copper and sixty parts of ferro-manganese, with a suitable quantity of some appropriate flux, produces a metal of such tenacity that it surpasses the best steel armor plates. The melted mixture is cast in blocks and is perfectly malleable. To obtain a white metal that can be rolled out in sheets, the above alloy is melted again, and twenty or twenty-five per cent of zinc or white metal added, which imparts to it the desired quality. A plate of the first named alloy two inches thick was found by experiment to offer more resistance to a cannon ball than a steel armor plate of the same thickness. This new kind of "white bronze" is not to be confounded with the alloy used in this country under the same name for grave-stones and monuments, and which consists principally of zinc.

POST OFFICE FRAUDS.—The U. S. *Official Postal Guide* publishes a list of over 500 names of persons designated as frauds, and who conduct fraudulent lotteries and enter into other schemes to defraud the public, and to whom payment of money orders and the delivery of registered letters has been prohibited by the Postmaster-General. Of this large number, there is not one shown to reside in California, or any of the Pacific coast States or Territories.

CUCUMBER WOOD.—There is a kind of timber known as "cucumber wood" which is used in some parts of Ohio for siding, and is regarded as good as any wood for that purpose. Considerable quantities of cucumber are cut on the Mississippi bottoms, where it is cut into dimensions and made into boxes.

SHRINKAGE in lumber varies according to the tree from which it is made. Oaks will shrink in drying a half inch to the foot, while the redwoods of California show no perceptible change, and the heavy eastern or South American woods lose but little.

A LUMINOUS SLATE.—One of the most charming adaptations of Balmain's luminous paint is a magic slate, supplied by Messrs. Wolf & Son, which can be written upon in the dark with an ordinary leadpencil. The writing or drawing appears as so many lines of darkness surrounded by a background of light. Under many circumstances such a slate may be found very useful, but it cannot fail to be a source of much amusement. No phosphorus or other inflammable material is employed in the manufacture of the slate, its luminous properties being derived solely from its power of giving out light absorbed during the day. The writing or drawing on the slate can be easily removed by a moist rag or sponge, and the slate itself cannot be worn out, its luminous powers being re-excited by exposure to light from day to day. As a writing-tablet for desk or office the luminous slate may also be used, resembling, as it does, in color and form, the ordinary porcelain slate.

THE UTILIZATION OF SMOKE.—A company at Elk Rapids, Mich., which manufactures fifty tons of charcoal iron a day, formerly allowed the smoke made in burning the coal to go to waste. Now the smoke, as it is formed, is delivered into stills charged with lime and surrounded by cold water, the result of the condensation being first, acetate of lime; second, alcohol; third, tar; the fourth part produces gas, which is consumed under the boilers. A thousand cords of wood are converted into charcoal daily, yielding 2,800,000 cubic feet of smoke, from which are obtained 12,000 pounds of acetate of lime, 200 gallons of alcohol, and twenty-five pounds of tar. The alcohol has been contracted to a firm in Buffalo, N. Y., the *Trade Review* says, for five years, they furnishing the packages and receiving it at the works at eighty cents per gallon.

HOUSE MOVED BY A TREE.—A large elm tree at Norwich, Conn., has moved a house by the force of its growth. The tree is more than seventy years old, and the trunk reaches a height of thirty feet before a limb branches out. During the March winds the limbs spreading over the house swept off part of the chimney, and it was removed. The tree, which stands at the northeast corner of the house, has grown so large that it raised and moved the house one foot from its original position.

A COUNTRY WITHOUT HOUSE-FLIES.—Housekeepers will be interested to learn that there is one country in the world where the common house-fly is almost unknown. That is the Philippine Islands, and the phenomenon is explained by a writer in *Science*, who says the fly could not, by itself, traverse the 600 miles of windy ocean lying between the islands and the mainland, while the few flies that arrive at Manila in vessels fall victims to voracious insect enemies.

GOOD HEALTH.

Variations of Digestion.

Of course it is impossible to reduce digestion to a positive science in its relations to different persons, the time varying according to diverse circumstances. After a fast of several hours, when the appetite is keen and the powers are in their best conditions, active and fresh, it is reasonable to infer that a meal will be digested in very much less time than when these powers are debilitated by excessive labor, fatigue and depression. Like the body, as a whole, the stomach may be active, energetic, and prompt in its labors. For the same reasons, the digestion of one accustomed to vigorous labor in the air and sun, with an unusual amount of the waste of the tissues as the result of such labor, will be far superior to that of one of sedentary habits, and the indolent, with little waste and with far less demand for the repairs of a wasted body. While both do not demand the same food in kind and amount, it is evident that the time of digestion will vary. It is proper to add that neither violent exercise nor absolute indolence are favorable to digestion, but moderate exercise. It is also true that digestion is impaired and retarded by violent mental labor, by grief, anxiety, anger, all violent emotions, such as divert the blood from the stomach to the brain, robbing digestion of its vital forces. Even sadness and discouragements impair the digestive processes, while cheerfulness, hope, and buoyancy of spirits produce the opposite results. "Laugh and grow fat."

Of course, digestion in the young and vigorous, the growing child, demanding food for daily use for repairs, in addition to that needed for growth, must not only be active and prompt, but such will demand more food relatively than the adult. The same is true of one emaciated by disease, since there is a greater demand for the repairs of the wasted tissues; and yet there is a limit.

It is possible to exceed the amount demanded in such cases, by which excess the stomach may be so far taxed as not to be able to digest enough to meet the real wants of the body, or it may do this labor so imperfectly as measurably to defeat the design of eating, that of giving health and strength. Even the "growing boy" may eat so much as to weaken the digestive powers to that extent that only a small part of the food taken will be of any value. The food fairly and thoroughly digested only can be of much service, while that undigested, remaining in the stomach to ferment and decay, not only is of no

service, but must contaminate the body, inducing disease. It is quite certain that most of the lassitude, the feeling of fatigue in the morning, is attributable to the absence of rest and sleep occasioned by a late meal, taken at bedtime, it may be, or to a too full meal at the usual time, by which the organs of digestion are so taxed, overworked, as to produce this general feeling of fatigue. These organs may as certainly suffer from labor, toil, as the body as a whole, resulting in a general fatigue, an unrefreshed state of the whole body. Dr. J. H. Hanford.

THE EYE.—If one would have clear and good sight, keep the stomach in a good condition, by the use of simple, nourishing and easily digested food, taken at proper times, and never rob the eye of its great food-stimulus—the light of the sun. Seeing is as natural as breathing, when no obstacles are presented. We breathe without effort naturally, but if the chest is bound and constrained, it is difficult. So with the sight. We have simply to open the eye and it sees naturally and without effort, under favorable circumstances. I know of no better eye-water than pure, soft water, bound with a wet cloth over the eyes, if inflamed or painful. I know of no better medicine than the light of the sun, not so bright and dazzling as to be painful. Even in sickness, with some modifications, a reasonable amount of clear sunlight is an advantage, at least in the room, the eye being covered by a wet cloth, if painful. If we would have good sight, away with stained glass, dark curtains, veils, shades, blinds, "banged hair," or all hair through which one attempts to see. Do not attempt to read, study or work when the light is not a good one, always preferring natural light to artificial, doing as little work at night as possible. Do not use a flickering light or read in the cars to save time. Do not use the eyes at the twilight hour, or under any circumstances particularly trying. Open the eyes and let them see, instead of compelling them to see.—Dr. J. H. Hanford.

RIGHT LIVING.—It is preposterous to suppose that we can live as our sensual impulses may dictate, outrage all common sense, violate all of the laws of our being, and then escape the penalty. We cannot live like swine and rise to the position of angels. Disease is no accident, but has causes as certainly as have bruises, sprains, broken bones, and the like. Derangements, disease, pain, suffering, and premature death are the direct outcome—the results—of the violations of the laws of the body, or the laws of God, in general, visited upon us as penal inflictions. There is no accident or uncertainty in the matter of securing health by obedience to the laws and conditions of health. There is no more uncertainty in securing it than there is in obtaining an education, in learning a trade, or in succeeding in any branch of business. Seeking health is a legitimate business, and is far more promising and certain than the mercantile, since there is no danger from competition, and very few obstacles in the way, save our own sensual weaknesses. As a general principle, the climate is far more favorable than our own habits. We can obey and succeed, or disobey and suffer. In this we are free to act, and are the architects of our physical fortunes, as much as in business.—Dr. J. H. Hanford.

MULLEIN AS A REMEDY FOR COUGHS.—Dr. Quinlan, of Dublin, who last year read a paper at the British Pharmaceutical Conference on the homoeopathic properties of the *Plantago lanceolata*, has recently investigated the properties of the common mullein, *Verbascum thapsus* (*British Medical Journal*, January 27, p. 149). This plant has long been used in Ireland as a domestic remedy for consumptive cough, and Dr. Quinlan has made a series of experiments with a view to determine if it really possesses the valuable properties attributed to it. He finds that when boiled in milk the patient takes the decoction readily, and experiences a physiological want when it is omitted. Its power of checking phthisical looseness of the bowels and the relief afforded to coughing were very marked, so that the patient took hardly any other cough mixture. In early stages it appears to have a distinct power of increasing weight, but in advanced cases Dr. Quinlan remarks that he is not aware of anything that will do this except koumiss.

SNEEZED SIX DAYS.—The Ithaca (N. Y.) *Journal*, of a recent date, says that Mrs. Harrison Thayer, who lives on Jersey Hill, in the town of Danby, began sneezing Tuesday. After eight hours' continued sneezing the family became alarmed and called a physician, who could not account for the strange attack and could only ease the lady by administering chloroform. But this only effected a temporary cure, for no sooner does Mrs. Thayer become conscious than she begins sneezing again. On Monday she was still at it. A second physician was called in, and both say they never knew such a case before.

BEWARE.—The *Sanitary Engineer* gives this valuable piece of advice to housekeepers: Beware of disused "conveniences," and don't trust to the memory of any one for filling the visible trap with water. Better remove the whole fixture and seal up its outlet if not wanted for frequent use. Moreover, don't you put such an antiquated device as a pan-closet in a first-class house anywhere. Even if its receiver be ventilated, the vent-pipe may work the wrong way and deceive you.

TABLE OF CONTENTS.

EDITORIALS.—Swedish Blast Furnace; Pacific Coast Mining Exposition; Machine Mining Drills, 305. The Salmon Interest of the Northwest; The Salmon, 30. Passing Events; Catching Float Gold in Streams; Mining and Metallurgical Appliances; Copper Mining on the Pacific Coast, 312. The Brooklyn Bridge, 313. Patents and Inventions; Notices of Recent Patents, 36.

ILLUSTRATIONS.—Shaft Sinking and Drifting with Machine Drills; Plan of Swedish Furnace; Swedish Furnace for Copper; Starting a Tunnel, 305. Group of Salmon; Salmon Fishing Station on the Columbia River, 310. View of the New York and Brooklyn Bridge, 313.

MECHANICAL PROGRESS.—Sources of Injury to Boilers; A New Style Locomotive; Power of Belting; How to Select a File; What Next; The Effects of Punching on Metals; Cold and Hot-Short Iron, 307.

SCIENTIFIC PROGRESS.—The Storage of Electricity; The Great Red Spot on Jupiter; The Electro-microscope; Photomicrography, 307.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Meetings, Assessments, Dividends and Ballot Shipments, 308.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico and Utah, 308-9.

THE ENGINEER.—Screw in Tunnel; American Engineering; The Hudson River Tunnel; The Tehuantepec Ship-Railway; The Panama Canal, 311.

USEFUL INFORMATION.—Cleaning Watches with Benzine; Solidified Milk, Oil, Whiskey, etc.; White Bronze; Post Office Frauds; Cucumber Wood; A Luminous Slate; The Utilization of Smoke; House Moved by a Tree; A Country Without House Flies, 31.

GOOD HEALTH.—Variations of Digestion; The Eye; Right Living; Mullein as a Remedy for Coughs; Sneezed Six Days; Beware, 311.

NEWS IN BRIEF.—On page 316 and other pages.

MISCELLANEOUS.—English Investments in the Pacific Coast Mines—No 3; The Immigration Association of California; Southern Nevada, 303.

BUSINESS ANNOUNCEMENTS.

Reliance Machine Works—Clot & Meese, S. F.
Elevator Works—Philip Hinkle & Co., S. F.
Chemical Sawnware—Richard C. Remmey, Philadelphia.
Hydraulic Giant—Hoskin Bros., Marysville, Cal.
Sackett School—D. P. Sackett, Oakland, Cal.

Passing Events.

The news from the mining regions seems everywhere favorable just now. From various places come notices of new strikes. Down in the southern part of this State a new camp has been opened. Up in Idaho new coal fields have been found near Horseshoe Bend. Encouraging reports from Clark's fork and Emigrant gulch, Montana, are received. A "stampede" from Montana into Washington Territory is now going on, new mines having been discovered there. They are gold diggings of which but little is so far known. In this State people are now expecting a very prosperous year, both the mining and agricultural community being satisfied with the prospects.

NEW MINES.—A new mining district, called Poorman's, at Mesquite, on the Colorado desert, this county, has been located within the last two weeks. The mines are situated one mile in an easterly direction from Douglas Peak, and half a mile southwesterly from Flag Staff Peak. The Southern Pacific passes within a short distance. Following are the names of the mines that have been located, the assays from which are reported to be enormously rich: City of Chicago, Esperanza, True Fissure, Outside, Los Amigos, Kate West, Ocotilla, Buffam, City of New York, Crescent City, Mand and Maggie, Great Expectation, Kersage, Sand Storm, and Nameless.—*San Diego Sun.*

THE North San Juan Times says that North Bloomfield, a hydraulic camp, is one of the liveliest places in Nevada county and a reminder of the early mining days.

Catching Float Gold in Streams.

We often hear mining men tell of the large quantities of float gold which pass down the streams of this State where mining is carried on, or which receive the waters of other streams where men are mining. No one seems to have thought it possible to catch any of this float gold after it passed out of the sluices into the streams themselves. Yet in other countries the people avail themselves of the opportunity afforded on streams where mining is done to catch the float gold—for it really does exist. It has been found, for instance at Charleston, New Zealand, that the gold does not all settle in the tail races, but that, in the union of the water of several tail races, a small percentage, well worth saving, floats away.

The gold is arrested by a method termed "fly-catching," which consists of a series of blanket-tables placed across stream, like weirs, so that the waters shall flow over each table in succession. The tables are washed in turn, and the gold is streamed from the sand and caught up by quicksilver. Many of these "claims" yield from \$20 to \$45 per week, with little labor. In the Charleston district referred to, fly-catching has become quite an industry in itself, and no doubt there are quite a number of places in this State where similar stations could be maintained with profit.

The tables are constructed entirely of timber. Piles two or three feet in length are driven firmly into the bed of the creek and on these are nailed lengths of stout quartering, covered over with one inch-boards laid close together, so as to form a smooth table. Pieces of lighter quartering are then placed over the boards from top to bottom, forming divisions about four feet in width. Blanketing or cloth—ordinary grain sacks opened out—are frequently used—is next spread smoothly along these divisions and securely fastened down by small strips of wood. The tables vary in length from seven to twelve feet, and are placed in the creek at intervals of from sixty to 100 feet, extending quite across the stream. The proprietors of these rights are said to realize during rainy weather very good returns, ranging from \$10 to \$30 a week, according to the nature of the workings on the banks above and the number of tables set in the creek. The tables are liable to damage by flood. The tables are made in compartments and when the blankets are lifted out of one compartment, spare cloths are kept to replace those lifted. The men wash out the cloths once or twice a day, in a box by the side of the creek. The fine tailings pass over several sets of tables in their course down the creek.

Shoes and Dies for Amalgamating Pans.

As ordinarily constructed amalgamating pans receive the pulp and tailings from the battery, and are provided with dies on the bottom of the pans and shoes which are fixed to a revolving miller, so as to be moved over the dies and in close contact with them, while the pulp is caused to pass between these moving surfaces, where it is ground in the presence of quicksilver, so that the latter may amalgamate with any particles of gold or silver, and take up any quicksilver or amalgam escaping from the battery or other previous apparatus. These iron shoes and dies are subjected to considerable wear by the sharp sand passing between them, and more or less iron is taken up with the amalgam, which is thus rendered base; and it is difficult to separate the gold and silver contained in it. The iron has, of course, no particular affinity for the particles of gold, silver or amalgam, and is of no assistance in arresting them. A new idea in amalgamating pans has just been patented through the MINING and SCIENTIFIC PRESS Patent agency, by Johnson & Osborn, of Dos Cabezas, Arizona. They propose as a new article of manufacture shoes and dies for amalgamating pans, formed of silver. The silver amalgamates readily and presents a surface having a strong affinity for any particles of gold, silver or mercury, and will arrest the latter even when in its most difficult condition to save—when it is finely divided or "floured."

In some cases the shoes are in the form of rollers which rotate as they pass over the dies, and the pulp is caused to pass between the surfaces of the rollers and the die, the great affinity of the amalgamated silver causing it to take up the passing valuable particles with great avid-

ity. In this case the inventors think there is little need of the scouring or grinding action of flat shoes and dies. These shoes and dies may be used in what are known as "continuous pans" in which the pulp is fed in at the center and is discharged continuously at the periphery of the pan. These silver shoes and dies add to the amount of silver by their wear, so absolutely nothing is lost, and there is no additional expense created to separate out base bullion afterwards. Of course, these inventors know that copper or silver plates have been used in amalgamating pans where there was no considerable amount of grinding necessary, but only such friction as will brighten the particles and enable them to adhere to the silvered surface. The silver shoes and dies, however, are new articles of manufacture.

Mining and Metallurgical Appliances.

In some respects the newer mining regions of this coast have an advantage over the older, aside from the fact of having new mines to work. They have the experience of others as a guide and are not compelled to experiment so much. For instance, when new mines are found and it is contemplated to erect reduction works, there is not any necessity of experimenting with half a dozen processes. Metallurgists well know how the same kind of ore was worked elsewhere, and the experiment of the older camp need not be repeated.

Of late years, moreover, the mechanical appliances of mining have been very thoroughly perfected as long experience has dictated. There is now no danger of getting mills which are rattle-traps—provided reliable foundrymen are the makers—or furnaces which are mere stoves.

First-class metallurgical plants are now fitted out ready for use by the foundrymen making a specialty of this kind of work. For copper and lead, excellent furnaces, admirably adapted to their work, and with all improved attachments, are furnished ready to be set at work immediately. The old-fashioned masonry and heavy fittings are dispensed with, and water jackets, improved tuyeres, blowers, etc., make the modern style far ahead of what was known a few years ago. Copper and galena mines profit by this greatly, and first cost of plant is largely reduced.

Pans and settlers have become simplified, and instead of two or three dozen kinds, a combination of the best points of the best has been effected, so that there are now no longer experiments in that direction to be undergone with every new mill. With batteries and mortars, we have settled down to a type which has stood the test of experience of years, and all make the same style, with but few modifications. The number of concentrators has not increased, but has decreased. That is, a few styles having proved successful, economical, and good, have been adopted, and dozens of experimental machines so much heard of a few years ago have disappeared. Amalgamating appliances have been invented and patented in great numbers, though comparatively few have been applied in practice. In most of the best mills the same thing in this case will be seen.

Of the many different styles of roasting furnaces but few have stood the test of actual experience, and these few have been improved gradually to great efficiency. In the matter of leaching, practice differs more or less with the classes of ore, but the best metallurgists agree pretty well on the main points. Hoisting engines of different types are used, but the same general principles govern the construction of all. In pumping appliances there is perhaps more range than in any other thing connected with mining. Yet for deep mining work only certain styles of pumps are used. The only innovation is that of pumping by hydraulic power, as carried on now on a large scale at the Comstock and at Eureka, Nevada, and quite successfully. This system will gradually spread, no doubt, and other mining camps will have hydraulic pumps.

In the matter of rock drills and compressors, there is a great variety, though three or four styles seem to keep their places, as they do good and efficient work and have stood the test of every day experience.

People used to spend a great deal of money experimenting with new appliances and processes, in hopes of getting something better than their neighbors. A new mining company, with new men as managers, was very apt to do this. Now, however, it has been found to be best to be careful in this respect. New companies are now more apt to get the very best appliances of all kinds combining the experience of all who have gone before.

Copper Mining on the Pacific Coast.

The Business in California.

For a number of years following the collapse of the Copperopolis mines the business of prospecting for and mining copper ore was much neglected in California. What little ore was extracted during the twelve or fifteen years that followed the abandonment of the Copperopolis mines was nearly all shipped out of the State, scarcely any attempts having been made at working it here. That the business received so little attention during this long period was owing to the great decline that took place in the price of this metal at the close of the war and the difficulty that has attended the reduction of the California copper ores, which are not usually of high grade, while they are largely of the sulphureted variety, rendering them troublesome to treat. The cupriferous ores occur in a great many places in this State, the deposits being very numerous along the foothills of the Sierra Nevada. In Del Norte county several large veins have been discovered and worked to a limited extent, the ores there being extremely rich.

Beneficiating the Low Grade Ores at Spenceville

Notwithstanding the drawbacks mentioned, it may be expected that this industry will be gradually revived in California, the method of treating these low grade sulphureted ores adopted by the San Francisco Copper Mining Company, having demonstrated that they can be reduced with profit. The mine and works of this company are situated at Spenceville, Nevada county. Their ore is abundant but assays only from four to ten per cent metal and is nearly all of the sulphureted variety. Not until ten or twelve years had been spent here in futile efforts, was a method hit upon by which this ore could be successfully handled. This accomplished, the business of beneficiating it has been prosecuted for the past five or six years on a large scale and with satisfactory and steadily increasing profits.

The leaching plan adopted by the San Francisco company, long used in Germany and Spain, may be briefly described as follows: The ore is first roasted by being placed in great piles on layers of wood, these piles containing usually as much as 1,000 or 1,200 tons each. The wood once fired, combustion is kept up by the burning of the sulphur in the ore until the latter becomes practically desulphureted. This roasting process proceeds slowly, from four to six months being required for its completion. The sulphate produced by roasting is placed in wooden tanks and leached. The solution thus obtained, after being transferred to reservoirs and settled, is pumped into revolving cylinders, where the copper is precipitated through the agency of scrap iron. Two or three tons of the precipitations having accumulated in each cylinder, they are removed, filtered, and transferred to the drying pan, which, expelling the moisture, leaves the product in the form known as precipitate, or cement copper, which, assaying between eighty-five and ninety per cent fine, is in shape for market. By the above process, from forty to fifty per cent of the metal is extracted from the ore treated, the balance being obtained from the dump pile after it has undergone spontaneous decomposition. As this method of procedure is cheap and simple, and entirely practicable, wood and water being plentiful in all the cupriferous districts of California, it may reasonably be expected that it will soon come into extensive use here, insuring an early revival of this industry in the State.

Copper Deposits in Nevada.

During the period that copper mining remained so depressed in California, valuable bodies of this ore were discovered and in some instances extensively developed in both Nevada and Arizona. The first considerable deposits in the State of Nevada were discovered as much as ten or twelve years ago. They are situated in the Pine Nut Mountains at a point about forty miles southeast of Virginia City. The veins in this locality, several in number, are from six to ten feet wide, trend north and south and lie between limestone and quartzite. The ores, principally carbonates and red oxides, assay high in metal. A good deal of ore has been extracted here and sold to the blue stone works at Dayton, on the Carson river, none having ever been smelted or shipped to more distant markets. The gross product of these mines has amounted to over \$200,000. For several years past but little work has been done at this locality. As the Carson and Colorado railroad passes near them, it is probable ore extraction will in good time be resumed at these mines. Fifty miles further on, in the northeastern part of Esmeralda county, there exists a copper bearing range of great magnitude, the most of it being embraced within the Santa Fe and Soda Springs mining districts. These deposits were discovered and some of them located many years ago; but being in a desert region and far from available shipping points, little or nothing was done towards their development until within the past year or two, the advent of the Carson and Colorado Railroad in that section of country having led to renewed attention being given to these deposits, the most of which have since passed into the hands of parties having the means and enterprise to properly explore and bring them into a productive

condition, vigorous measures to that end having already been adopted.

The Santa Fe District.

Covering an area of fifteen miles by ten, lies in the mountain range that bounds Soda Spring valley on the north. To the northeast of it lies Gillis Mountain district and to the east, Arlington Spring arroyo. Within this area a large number of copper bearing lodes occur, many of which are being exploited. Some of these lodes show ore fissures of great strength and promise, carrying at or near the surface the most desirable and docile character of copper ores of a high tenor, ranging from twelve to sixty per cent. These ores consist of red and black oxides, (cuprites and malachites) blue and green carbonates (malachite azurite and silicates) with exceptional spots of sulphides (glance and peacock). One very strong vein carries native copper in sufficient quantities for stamp work. These ores are all singularly free from arsenic and antimony.

In the district are the following important groups of mines: The Sweet Vengeance, Stone Cabin, Jersey Blue, Copper King, New Camp, and the Brady's Camp, each group containing from four to eight distinct veins within a comparatively limited area, the nearest group being distant from Luning, on the railroad, two miles, and the furthest six miles, affording facilities for cheap transportation of coke and material to the mines and of the bullion product to a market.

These lodes, nearly all of which are gossan capped, crop boldly, coursing, as a rule, north-erly and southerly with the strike of the mountain range. With rare exceptions, east-erly and westerly veins occur—the most prom-ising are contact deposits lying between syenite and porphyry, or lime slate, dolomite and quartzite. The gangue is invariably silicious, and is found more or less with calcareous mat-

In addition to these arroyos, which afford natural roadways of easy grade from the metal bearing lodes to the valley, the ranges are di-vided lengthwise by washes or smaller valleys. This district must become, at no distant day, an important agent in the copper-producing factors of the world.

The town of Luning, on the railroad, is the shipping point for the Santa Fe, and also for Gillis Mountain, Garfield and the Silver Star districts, the valuable minerals in the latter three consisting chiefly of silver-bearing ores. Luning is an active and growing place, with the prospect of becoming in a few years quite a large town. Twelve miles south of Luning brings us to Soda City, so-called from two re-markable springs in the neighborhood, one hot and the other cold, but the waters of both possessing valuable medicinal properties. Soda City, like Luning, is a thrifty hamlet, being on the railroad and the shipping station for

The Soda Springs Mining District.

Lying adjacent. The deposits here are cuprif-erous, the geology of the country as well as the vein system and the character of the ores, being similar to those in the Santa Fe district. The greater portion of the more valuable lodes in this district are owned by the Esmeralda Cop-per Mining Co., the only parties who have as yet put up copper reducing works in this region of country or performed any very large amount of exploratory labor on their mines, some of which give incontestable evidence of large value. As at Santa Fe, the lodes here are large, shape-ly and compact, carrying rich ores in good body from the surface—which means profit from the start. These ores also contain their own fluxes, carrying lime and iron in about the proper proportions for effective smelting. A good deal of the ore here assays from 40 to 50 per cent. cop-per. This company have put up at Soda springs a 30 ton smelter, which for some time

The Bell Smelter.

The *Inter-Mountain* (Butte, Montana,) says: Next to the location of the Anaconda smelter, perhaps the most important question which has agitated the public mind in this city during the past six months has been the resumption of operations by the Bell company. With plenty of ore in the mine and with a smelter in fine shape for reducing an abundance of its prod-uct, there has been no doubt that a splendid financial success would follow the beginning of operations under the new management; but not till yesterday was it positively known when the furnaces would be fired up. In conversa-tion yesterday with Walter J. King, acting manager of the company, it was learned that at twelve o'clock to-day, in all probability, one of the blast furnaces, having a capacity of thirty tons daily, would be fired up, and if not to-day that Saturday would be the latest time when operations would be resumed.

The smelter is under the immediate charge of Prof. Pitman, whose reputation as a practical and scientific metallurgist is a sufficient assur-ance that the works will be conducted in the most economical and successful manner.

The ore supply at the smelter is abundant, there being 3,000 or 4,000 tons of ore already delivered and available for immediate reduc-tion. The vast amount of ore, it is estimated, will keep one furnace supplied for about three months, at the expiration of which time it is expected that the main three-compartment shaft at the mine, which is now 180 feet deep, will have attained a depth of 400 feet, and that the ledge will be fully opened through a north crosscut from the bottom station, thus allowing the easy and comparatively inexpen-sive extraction of all the ore the smelter can treat, with both furnaces in operation.

The news that the Bell smelter has resumed

The Brooklyn Bridge.

The famous Brooklyn bridge to connect the prosperous cities of New York and Brooklyn, and which has been in course of construction since January, 1870, will be formally opened for traffic on the 24th inst. Mr. Jno. A. Roe-bling originally estimated the cost at \$7,000,000, exclusive of the land required which has cost \$3,800,000. The actual cost when completed will be about \$15,500,000. One reason of this increase was the Government required an in-crease of five feet in height, making the clear-ance under the bridge 135 feet, and it was wid-ened from eighty to eighty-five feet. These changes cost eight per cent more. Steel was substituted for iron, and the approaches are masonry instead of wire rope. The following figures give a good idea of the dimensions:

Length of each land span,.....	930 ft.
Length of main span,.....	1,595 ft. 6 in.
Height main span above water,.....	135 ft. 6 in.
Length of N. Y. approach,.....	1,562 ft. 6 in.
Length of Brooklyn approach,.....	971 ft.
Depth of N. Y. foundations, below high water,.....	78 ft. 6 in.
Depth of Brooklyn foundation, below high water,.....	44 ft. 6 in.
Total height above high water,.....	271 ft. 6 in.
Height of railway at tower,.....	119 ft.
Width of openings through towers,.....	33 ft. 6 in.
Diameter of cables,.....	15-3/4 in.
Number of wires in each cable,.....	5,434
Sustaining power of each cable,.....	12,000 tons
Total length of wire in each cable,.....	3,515 miles
First wire rope stretched over the river, Aug. 14, 1876	
River first crossed on a wire rope,.....	Aug. 23, 1876
Footbridge finished and crossed,.....	Feb. 9, 1877
Commenced to build,.....	Jan. 3, 1870
From Sands St., Brooklyn, to Chatham St., New York, one and one eighth miles long.	

VIEW OF THE NEW YORK AND BROOKLYN SUSPENSION BRIDGE ACROSS THE EAST RIVER.

ter. Cupriforous ore bodies are also found on a highly crystalline lime stone (carbonate), but they are irregular and unreliable, only occur-ring in pockets or chambers, not sufficiently exten-sive for economic purposes, being soon ex-hausted. The ores of this district, by assay, show hut a small percentage of gold, but silver is often associated in sufficient quantities to materially add to the values of the copper prod-uct.

Iron (hematite) in dykes of considerable strength are found in the vicinity of these veins well adapted for fluxing purposes, though the veins themselves often carry their own fluxes—iron, lime or silica. The hills are sparsely tim-bered with nut, pine and juniper, and springs of good water are not infrequent in this range of mountains. Soda Spring valley, through which the C. & C. R. R. runs, has undoubtedly been, at some remote period, a southerly arm or extension of Walker lake. The resident In-dians have a tradition to that effect, and the water lines on the base of the surrounding mountains are plainly to be seen. Artesian water in abundance can no doubt be obtained at almost any point in the valley, as wells sunk to a depth of thirty-five feet invariably get an inexhaustible supply. The general elevation of the range above the valley is some 2,000 feet; the altitude of the valley above the sea level 4,000 feet.

Geological Formation.

These mountains are in the main metamor-phic, ranging to cambrian or lower silurian, and exhibit a succession of gray and black lime-stone strata, alternating with crystalline meta-morphic schists, vastly disturbed, tilted and broken extensively by massive intrusions of porphyritic and granitic rocks. There has been extensive erosion throughout, as is evinced by the sharp fissuring of the naked strata, and in the numerous deep arroyos that cut the mountain chains in a course generally trans-verse to their trend.

past has been turning out black copper, 96 to 97 fine, at the rate of five tons per day. They employ about 53 men—23 at the smelter and 30 at the mine. At present they are working but one of their several veins, this, the Blue Light, affording ore enough to keep the smelter fully employed. As they appear to have ore enough, an additional furnace will probably be erected before long.

The ore they are now reducing gives average assays eighteen per cent copper, though the company could profitably beneficiate this tract-able class of ores carrying not over ten or twelve per cent metal. They have a side track from the railroad to their smelter with a branch on each side, one for bringing in coke and other supplies and the other for carrying out bullion. There is wood enough in the vicinity for making steam, but English coke is used here for the smelter. This company being made up in part of parties interested in the famous Copper Queen mine of Arizona have aimed to admin-ister their affairs on the same sound and econ-omical basis adopted in opening up and out-fitting the above property. They run in debt for nothing. Expenses that cannot be fully met from the net earnings of the mine during its earlier stages of development are provided for by the sale of enough stock to make up the de-ficiency, and no more,

FRUE CONCENTRATORS. — In December last Mr. P. C. Du Bois put into the Gold Blossom mill at Ophir, Placer county, this State, two Frue and two Triumph concentrators, both of which machines separate the gangue from the mineral by an endless rubber belt. The ma-chines referred to have run side by side for several months. A short time since Mr. Du Bois desired to increase the capacity of his mill, and we are informed he has ordered five more Frue concentrators, indicating that after trial he was convinced of their superiority, and preferred them even at the increased price,

operations will be welcome to the entire com-munity, and particularly so to the patient stock-holders, who, though disappointed by the failure of the old management, have always expressed faith in the richness and productiveness of the mine, and many of them by personal inspection know it to be one of the most extensive and promising copper properties in the west. The energetic and economical management of Mr. James King has inspired all with a feeling of great confidence in the future, and it is consid-ered certain that hereafter the Bell company, as far as the success of its management and out-put are concerned, will take rank with the companies managing the Montana, Parrot or Colorado smelters.

THE statement is made by some of our miners that the charges of the Howell Company for the reduction of ore, added to the high rates for transportation, excludes all ores of a less assay value than \$100 per ton from treatment at Lynx creek. As the Howell Company are said to have enough ores of their own to oc-cupy their works to their fullest capacity for some years, it might be of advantage to our business men to consider the question of of-fering some inducement to millmen, who would undertake the erection of works that would meet the wants of the miners above referred to.—*Prescott Courier*.

THE Nevada (Cal.) *Transcript* says: Sunday, a 200-pound boulder, very rich in gold, was found in the Chinese claim situated on the south side of Omega, just below John Goyne's residence. The Chinamen refuse to give the value of the boulder, but it is said to contain a large quan-tity of the royal metal.

THE Carbonate Hill Mining Company has de-clared a dividend of five cents per share, or \$10,000, payable May 2nd. This will make \$40,000 to that date.

The adoption of a suspended span of 1,595 feet, at a height of 135 feet, determined the height of the towers (270½ feet) from which the span must be suspended. The cables are anchored inland, 930 feet back from the towers on each side. The anchorages are solid buttrical struc-tures of stone masonry, 119 by 132 feet at the base and rising some ninety feet above high water. They weigh 60,000 tons each. The bridge floor is an immense steel framework, consisting essentially of two systems of girders at right angles to each other. There are stays in every direction. The weight of the whole suspended structure (central span) is 6,740 tons; and the maximum weight with which the bridge can be crowded by freely mov-ing passengers, cars, vehicles, etc., is estimated at 1,380 tons, making a total weight borne by the cables and stays of 8,120 tons, in the pro-portion of 6,900 tons by the cables and 1,190 tons by the stays. The lengthwise pull in the cables and to the load becomes about 11,700 tons, and their ultimate strength is 49,200 tons.

We have several times before alluded to the details of construction of this bridge, and now refer to it only in general terms. The engraving herewith gives a good idea of its general ap-pearance. A most magnificent view of the sur-rounding country may be had from the bridge. As an engineering feat the bridge is unparalleled and reflects great credit on its designer the late John A. Roebling and his successor W. A. Roebling. The Brooklyn bridge will hereafter be one of the "sights of New York."

THE March product of the Lexington mine of Montana was 76,575 ounces of silver and 799 ounces of gold.

A NEW company to develop the coal mines at Pinacate and vicinity has been organized at San Diego, and is known as the San Diego Coal Mining Company.

San Francisco Pioneer Screen Works
J. W. QUICK, MANUFACTURER.

Several first premiums received
for Quartz Mill Screens and Per-
forated Sheet Metals of every
description. I would call special
attention to my SLOT CUT and
SLOT PUNCHED SCREENS,
which are attracting much at-
tention and giving universal
satisfaction. This is the only
establishment on the coast de-
voted exclusively to the manufac-
ture of Screens. Mill owners using Battery Screens exten-
sively can contract for large supplies at favorable rates.
Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 12x20. This latter size furnished J. R. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 36x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars. Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Oster mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines

CORLISS ENGINES from 12x16 Cylinders to 30x40. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Fine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

THOS. F. ROWLAND, Sole Man'fr, Brooklyn, N. Y.

IRON SLUICE RIFFLE.

I have an Iron Riffle, adapted for Hydraulic, Drift and Quartz sluices, which is proving very efficient, below everything else. (Cost six cents per pound.) Address, ALMARIN B. PAUL,

Room 20, Safe Deposit Building, San Francisco

The following speaks for itself:

INDIAN SPRING DRIFT MINE, Feb. 25, 1883. Mr. A. B. Paul's—I have tried your Riffles thoroughly, and find them a fine Riffle. They are good with quicksilver or without. They gather the fine gold and rusty gold. I find gold that will not touch quicksilver stops in them, and which slides over 300 feet of sluice above them. I shall try 30 more, and if they save the same amount of gold in four weeks' run, I shall want 100 more. I am not afraid to vouch for them. B. G. McLAUGHLIN, Superintendent Indian Spring Drift Mine.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in Dewey & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR THE WEEK ENDING APRIL 17, 1883.

- 275,978.—STRAINER FOR WATER FAUCETS—Geo. F. Barrington, S. F.
 275,893.—DIRT SCRAPER—W. H. Daidrick, Salina, Cal.
 275,909.—DEVICE FOR REMOVING TIRES—N. B. Hervey, Santa Rosa, Cal.
 275,911.—FILE HANDLE—Geo. W. Hill, Starks Point, W. T.
 275,916.—PULLEY BLOCK—Jackson & Carter, S. F.
 275,842.—SPEED REGULATOR AND REVERSING DEVICE FOR ELECTRIC MOTORS—Molera & Celrian, S. F.
 275,865.—RUB-IRON FOR VEHICLES—D. Shelton, Santa Rosa, Cal.
 275,952.—CHANNELING RIVERS, ETC.—D. Spangler, Hanford, Cal.
 275,956.—SULKY PLOW—P. K. Stockton, St. Helena, Cal.
 275,963.—SEPARATING THE SEDIMENT, ETC., FROM SACHARINE JUICE OF SORGHUM—J. D. Vandenberg, Marshfield, Or.
 275,967.—TIRE SETTER—F. Winne, Orland, Cal.
 275,968.—FOLDING CRATE FOR FOWLS—Thos. F. Woodside, Modesto, Cal.
 275,969.—CRATE FOR FOWLS—Thos. F. Woodside, Modesto, Cal.

FOR THE WEEK ENDING APRIL 24, 1883.

- 276,217.—SEWER-GAS TRAP—A. Blatchly, S. F.
 276,223.—HARNESS BUCKLE—A. Cadwell, Petaluma, Cal.
 276,353.—CENTER BOARD—W. O. Christensen, Marshfield, Oregon.
 276,225.—SUPPLY APPARATUS FOR FEEDERS FOR THRESHING MACHINES—John P. Cobb, College City, Cal.
 276,365.—FRUIT PITZER—C. A. Curran, Albany, Oregon.
 276,530.—TRACTION WHEEL—Jos. Enright, San Jose, Cal.
 276,171.—CASE FOR CIGARETTES—E. J. Fraser, S. F.
 276,239.—CABLE RAILWAY—A. S. Hallidie, S. F.
 276,240.—TRAVELING BAG—A. S. Hallidie, S. F.
 276,241.—PORTABLE HANGING SCAFFOLD—J. H. Hanavan, S. F.
 276,244.—SUSPENDER HOOK—H. M. Heinemann, S. F.
 276,181.—DRY ORE CONCENTRATOR—Jos. Hubert, S. F.
 276,418.—SHOE AND DIE FOR AMALGAMATING PANS—Johnson & Osborn, Dos Cabezas, A. T.
 276,424.—LEMON SQUEEZER—Kelly & Wimmer, S. F.
 276,185.—STEAM BELL RINGER—E. Lawson, S. F. Cal.
 276,492.—HAIR SPINNING MACHINE—John Spaulding, S. F.
 276,493.—SEDIMENT COLLECTOR FOR STEAM BOILERS—John Spaulding, S. F.
 276,494.—CARPET BEATING MACHINE—John Spaulding, S. F.
 276,393.—WHEELED SCRAPER—L. A. Sweatt, Santa Clara, Cal.
 276,320.—HORSE POWER—W. H. Worth, Petaluma, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

DIRT SCRAPER.—Wm. H. Daidrick, Selma, Fresno Co., Cal. No. 275,893. Dated April 17, 1883. This invention relates to that class of dirt scrapers used in leveling land. The invention consists in adjustable runners upon which the bowl of the scraper may run when dumped, in adjustable draft bars, and in an adjustable stop to limit the dump of the bowl. The object of the several improvements is first, by adjusting the runners, to so regulate the height of the bowl, and especially its bit, from the ground, that the dirt shall be dumped either suddenly in one place or gradually discharged and scraped over the ground, as the necessity of the case may require; second, to graduate the power required to make the bit take hold of the ground, and to dump the bowl as may be desired; and, lastly, to limit the dump at any desired point.

LEMON SQUEEZER.—Albert C. Kelley and Geo. W. Wimmer, S. F. No. 266,424. Dated April 24, 1883. The lemon squeezer consists of two jaws suitably shaped to receive the lemon or other object. One of these jaws has two handles hinged to its sides, while the other has a stem extending back centrally between the handles, to which it is united by a knee lever, so that when the handles are closed the two jaws will be made to approach each other.

SEWER GAS-TRAP.—Ambrose Blatchly, S. F. No. 276,217. Dated April 24, 1883. This improved trap consists of a peculiarly-shaped chamber, in the bottom of which mercury is placed, so that a complete metallic gate or trap is formed to prevent the passage of gas. The chamber is made of glass or other transparent material to permit an inspection of its contents, and is of such a shape that the level of the mercury will not be raised too high when the water is passing through the trap.

SUPPLY APPARATUS FOR FEEDERS FOR THRESHING MACHINES.—John P. Cobb, College City, Colusa Co., Cal. No. 276,225. Dated April 24, 1883. This is an apparatus for receiving and conveying unthreshed straw to threshing machines. The straw is usually deposited from the stack or header wagon, on a table in close proximity to the feeder. From this pile the straw is raked down upon the belt by hand. This system is done away with by this invention, as a peculiar pan-shaped receiver is provided, and the mass of straw which is dropped into the receiver by the derrick fork, is distributed by revolving arms with teeth so as to be fed with regularity upon the carrier belt and by it carried to the threshing machine. The receiver is mounted on wheels so as to be transported from place to place.

WHEELED SCRAPER.—Leroy A. Sweatt and John Patzo, Santa Clara, Cal. No. 276,303. Dated April 24, 1883. This invention relates to the class of wheeled scrapers for grading. The improvements consist in a means for holding it at any inclination for dumping it, in a novel adjustable guard for the front of the scoop, in a means for turning the entire device in a small space, and in certain minor details of construction. The object is to provide a device for leveling or grading the ground, the scoop of which may easily be raised to transport the earth or held at any inclination, or turned to dump it, and one wheel, on account of the length of its frame will reach effectively the small elevation, and at the same time may be easily turned in a small space.

CABLE RAILWAY.—Andrew S. Hallidie, S. F. No. 276,239. Dated April 24, 1883. This is an improvement on the cable railroads such as are in use in this city and elsewhere, and with which Mr. Hallidie has been identified since their inception. The improvement consists in a novel construction of a cellular metallic covering for the tube, having a filling of wood or asphaltum, which provides a secure footing for horses, in place of the broad and slippery surface of iron, which is usually necessary to keep the sides of the slot from spreading. This cellular covering forms also a rigid boundary for the slot, in place of the iron ordinarily employed. The cellular metallic covering is made so as to be removable without disturbing the paving of the street.

PORTABLE HANGING SCAFFOLD.—John H. Hanavan, S. F. No. 276,241. Dated April 24, 1883. This is a hanging scaffold, which may be readily taken apart and packed for transportation. The great advantage of the device is that it leaves all underneath free, and a workman can be engaged under the scaffold at the wall without having it in his way, as is the case when platforms with legs are used. The adjustability of the brackets provides for high ceilings, where, after working within reach above, the floor may be lowered to allow the workman upon the scaffold to meet the highest limit of the workman below. By being hung from the joists it is entirely out of the way, and as firm as though supported from below.

CRATE FOR FOWLS.—Thomas F. Woodside, Modesto, Cal. No. 275,969. Dated April 17, 1883. The crate for fowls consists of an adjustable partition moving upon guides within the crate, and provided with an adjusting and locking mechanism, by which it may be secured at any desired point, and thus divides the crate or cage into compartments of any desired size. Another patent by the same inventor for a crate for fowls bears the same date. It is a peculiar construction by which the crate is made to fold or collapse after it is empty, so as to be convenient for shipping.

SULKY PLOW.—Philip K. Stockton, St. Helena, Cal. No. 275,956. Dated April 17, 1883. This sulky plow is specially adapted for use in vineyards, or for plowing such plants as are in rows. The invention consists in combining a right hand and a left hand turning plow, or two or more of them, on a frame, so as to fall toward each other, or away from each other, the plows being movable on said frame, so that the furrows can be thrown, two or more at a time, toward the center or away from the center.

SUSPENDER HOOK.—Harry M. Heinemann, S. F. No. 276,244. Dated April 24, 1883. This is an improved means of attaching suspenders to pantaloons or other similar garments so as to make a strong fastening not likely to be broken and at the same time one easy to be detached. It consists of a hook so formed as to receive the buttonhole or loop of the suspender, said hook being permanently secured to the waistband of the pantaloons.

HARNESS BUCKLE.—Alexander Cadwell, Petaluma, Cal. No. 276,223. Dated April 24, 1883. This improved article of manufacture consists of a harness buckle having a frame and tongue with bent point fitting a socket or hole on the front of the frame, and having under its front side projections or guards inclosing the sides of the strap.

HORSE-POWER.—Wm. H. Worth, Petaluma, Cal. No. 276,320. Dated April 24, 1883. This invention relates to certain details of construction of horse-powers, by which they are made simpler and stronger.

TRAVELING BAG.—Andrew S. Hallidie, S. F. No. 276,240. Dated April 24, 1883. This invention covers an improvement in bags such as are employed by travelers. It consists of a bag or receptacle formed in the usual, or any convenient shape, and having the ordinary exterior covering material, inside of which is a lining of flexible wire netting, to prevent the material being cut through and the contents of the bag stolen. The flexible wire netting, while it prevents the bag being cut open, will allow it to be folded or expanded nearly as freely as when made of the usual material, and within this may be the ordinary cloth lining, by which it is concealed from view. By providing this bag with a stout frame and good lock, it will be burglar-proof, and may be used to transport money or other valuables.

News in Brief.

The Chinese Minister in Washington has decided to establish a Chinese Consulate in New York.

The sacred vessels and the poor box of the Catholic church at Watsonville were stolen recently.

It is estimated that the Government loses annually \$500,000 by smuggling carried on along the Rio Grande.

The greater part of the Eastern excursionists who have just arrived in the State, have gone to the Yosemite valley.

Red cranes are quite plentiful on the plains about Santa Monica. They are frequently shot, and make excellent eating.

The ship laborers at St. Johns, N. B., have refused to work on vessels where steam power is used in loading. The reason assigned is the frequency of accidents.

The war-worn Tombstone rangers have returned to Tombstone, footsore and weary, and without any scalp at their belts. As is usual in such organizations, they quarreled among themselves.

It is considered improbable that the attack of the *North German Gazette* upon the American Minister involves his resignation. Sargent has had little direct intercourse with Bismarck since his arrival.

JAMES R. KEENE is selling out his picture gallery and will join his family in Europe this summer. Jay Gould bought a Rosa Bonheur cattle picture for \$16,000, and Henry Clews bought three other paintings for about \$25,000.

The Government has cautioned General Crook not to cross the frontier. His understanding with the Mexican authorities gives him the privilege of doing so. The Government evidently has received no official information of the result of his consultation with Mexican officials.

SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD.—We would call the attention of our readers and mining men in general to the advertisement in another column of the San Francisco Plating Works, E. G. Denniston proprietor, 653 and 655 Mission street. The silver-plated mining plates which Mr. Denniston manufactures have proved a great success in both quartz and placer mining, and are used everywhere. Mr. Denniston is running his works constantly, filling orders for the Pacific coast and Rocky Mountain mining States, Mexico, Central and South America, Australia, New Zealand, British Columbia and Alaska. This establishment is the most extensive and successful in the manufacture of these plates of any in the United States. The plates made here have proved durable and satisfactory. Full weight of silver guaranteed on every order. Over 2,000 orders have been filled. Owing to the great demand for these plates, and increased facilities, they will be sold at reduced rates. Quartz and placer miners would do well to call or send for price list.

A SURVEY has been made for the Oregon Short Line to run through Boise City, and orders have been given to stop further building on the old survey.

To STRENGTHEN and build up the system, a trial will convince you that Brown's Iron Bitters is the best medicine made.

EVERY FOOT WARRANTED.

NOTICE OF REMOVAL.

The Clayton Steam Pump and Air Compressor Works would respectfully announce that they will remove May 1st, to their new works, 45 and 47 York St., Brooklyn, N. Y. (near the approach to the New York and Brooklyn Bridge.)

STRENGTH

to vigorously push a business, strength to study a profession, strength to regulate a household, strength to do a day's labor without physical pain. All this represents what is wanted, in the often heard expression, "Oh! I wish I had the strength!" If you are broken down, have not energy, or feel as if life was hardly worth living, you can be relieved and restored to robust health and strength by taking BROWN'S IRON BITTERS, which is a true tonic—a medicine universally recommended for all wasting diseases.

501 N. Fremont St., Baltimore

During the war I was injured in the stomach by a piece of a shell, and have suffered from it ever since. About four years ago it brought on paralysis, which kept me in bed six months, and the best doctors in the city said I could not live. I suffered fearfully from indigestion, and for over two years could not eat solid food and for a large portion of the time was unable to retain even liquid nourishment. I tried Brown's Iron Bitters and now after taking two bottles I am able to get up and go around and am rapidly improving.
 G. DECKER.

BROWN'S IRON BITTERS is a complete and sure remedy for Indigestion, Dyspepsia, Malaria, Weakness and all diseases requiring a true, reliable, non-alcoholic tonic. It enriches the blood, gives new life to the muscles and tone to the nerves.

"Challenge" Ore Feeders.

OVER 1100 HAVE BEEN IN SUCCESSFUL OPERATION.

Awarded First Premiums at the Preceding and last Industrial Fairs of the Mechanics' Institute of San Francisco.

TWENTY PER CENT. MORE ORE CRUSHED WITH FIFTEEN PER CENT. LESS WEAR OF IRON THAN BY THE OLD METHOD OF HAND-FEEDING.

The opposite cut illustrates this recently-introduced Gulp and Spring Attachment, which replaces the Weight originally used, and results in an obvious improvement. The practical operation of the large number of these machines now in use demonstrates the fact that the principle upon which a perfect Ore Feeder must be constructed is that of a carrier and not that of a shoving table. Uniform feeding is no possible upon the latter plan. The ore must be evenly carried upon a steady, advancing plate or table to the line or point of discharge, and there be simply dropped. Jerky or spasmodically acting contrivances will not answer the purpose for feeding wet or sticky ores, nor for the ores of mines where they may change from sharp quartz to an intermixed material of quartz and earthy matter.

Thee Feeders are in Successful Practical Operation in the following Quartz Mills, and are giving Perfect Satisfaction to their Managers.

And in many other Mills in the Mining Districts of the entire United States, and as well in Nova Scotia and Australasia. The superiority of these Feeders over other manufacturers has been so thoroughly demonstrated that it is not deemed pertinent to cite the numberless instances of this fact.

Manufactured and for Sale by

THE "JOSHUA HENDY MACHINE WORKS,"

Nos. 49 and 51 Fremont Street, San Francisco, Cal.,

Manufacturers of Quartz, Saw Mill and General Machinery. Agents for "BAKER" ROTARY PRESSURE BLOWERS, WILBRAM ROTARY PISTON PUMPS, P. BLAISDELL & CO.'S MACHINISTS' TOOLS, and the Celebrated "HOT POLISHED SHAFTING," from the Akron Iron Company, Akron, Ohio. Also Manufacturers of New and Dealers in Second-Hand Boilers, Engines and all Descriptions of Machinery.

CATALOGUE AND PARTICULARS FURNISHED UPON APPLICATION.

ASSESSMENT NOTICE.

Seaton Gold Mining Company.—Location of principal place of business, San Francisco, California; location of works, Drytown, Amador county, Cal.

Notice is hereby given that at a meeting of the Board of Directors, held on the 10th day of April, 1883, an assessment (No. 2) of even and one-half cents (7 1/2) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Treasurer, A. Warner, at his office, No. 224 Kearny street, room 2, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 14th day of May, 1883, will be delinquent and advertised for sale, of public auction, and unless payment be made before, will be sold on Tuesday, the 5th day of June, 1883, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. A. MARTIN, Secretary.

OFFICE—Room 6, 528 California street, San Francisco, California.

QUICKSILVER.

THE CELEBRATED A BRAND.

Shipped Direct from the New Almaden Mine, New Almaden, Santa Clara Co., Cal.

For sale in any quantity. Trademark A group of Flasks secured by United States Patent, and registered. Alaska contain 70 lbs. Quicksilver. Weight and purity warranted.

CARLOAD LOTS will be shipped from San Jose, Cal., by the Nevada, Arizona, New Mexico, Montana and Idaho, or Utah, or delivered at Pacific Mail Steamship Co.'s wharf, and Depot of S. P. R. R. Co., San Francisco, without charge. Railroad rates from San Jose are the same as from San Francisco.

Philadelphia Chemical Stoneware Manufactory,

1100 East Cumberland St., PHILADELPHIA, PA.

Manufacturer of all kinds of Chemical Stoneware—FOR—Manufacturing Chemists. Also Chemical Bricks for Glover Tower.

EXCELSIOR BLASTING POWDER,

Manufactured by the

EXCELSIOR POWDER COMPANY.

This is no new, patent, non-explosive Safety Powder, but the Genuine Standard Nitro-Glycerine Powder, as safe to use and handle as any other Nitro-Glycerine Powder manufactured. The fumes and gases, common in nitro-glycerine powders, are destroyed, and do not leave the miner with headache or nausea.

The powder is put up in cartridges of any size to suit the consumer, and is exploded in the same manner as all other high explosives; that is, by means of cap and fuse, or by electricity. It is not claimed for this powder that it is a non-explosive, or safer than other nitro-glycerine powder. All powder, and especially nitro-glycerine powder, should be handled carefully. The EXCELSIOR POWDER is as safe, and for strength far surpasses any other powder on the market. Address all orders to:

EXCELSIOR POWDER COMPANY,

Room 9, No. 3 California St., San Francisco, Cal.

Pacific Rolling Mill Co.,

CASTINGS AND FORGINGS OF EVERY DESCRIPTION.

Sole Manufacturers of Kendall's Patent Quartz Mills.

THE ROLLER ORE FEEDER.

Patented May 28, 1882.

This is the best and the most Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or cost a dollar for repairs.

Golden State and Miners' Iron Works, Sole Manufacturers, 237 First Street, SAN FRANCISCO, CAL.

PELTON'S PATENT Reaction Hurdy Gurdy Water-Wheel.

This wheel will be guaranteed to purchasers to give 80% of the theoretical power of water. See book for circular to L. A. PELTON, Nevada City, Nevada Co., Cal.

THE ALBANY CYLINDER OIL

Has its globule undisturbed, stands a fire test of more than 500 degrees, is perfectly free from acids or oxygen, clings with more tenacity to the metal, and exerts more the great pressure and heat of steam than any other lubricant.

LARGEST STOCK OF

GENUINE EASTERN OILS

In this City.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

—OR—

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ore is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for. That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

Improved Form of HYDRAULIC GIANT

We call the attention of those using or interested in Hydraulic Mining Machinery to the above cut of an improved form of Hydraulic Giant, in which it will be observed that the Deflector and heavy weighting rear part are abolished and a lever attachment, working with a ratchet and pawl substituted, by which the pipeman, standing in the rear of the machine, has, without danger of "hucking," full control of the direction and effect of the stream. In an action in the U. S. Circuit Court, entitled F. H. Fisher and Joshua Hendy vs. Richard Hoskins et al. of the Marysville foundry, a permanent injunction has recently been ordered against all persons manufacturing or using any form of Hydraulic Machine having the equivalents of the above.

All of the usual sizes are manufactured (under an exclusive right) and for sale at reduced prices by JOSHUA HENDY, at the

VOLUME XLVI
Number 19.

Electric Light for Street Lighting.

Within the past few years probably nothing in the scientific world has attracted so much attention, as the questions connected with the use of electricity; more particularly those referring to lighting and power. In the matter of lighting great strides have been taken, and the problem of the use of the electric light for streets has been solved, the system gradually forcing its way into favor. The Brush system has been applied in so many places now, that it has passed the experimental stage, and experience has proven its utility.

In this city a large establishment furnishes light to individuals, and in front of many large buildings and places of business the light is conspicuous. In San Jose the tower plan has been adopted, as we described and illustrated a few months since. In Los Angeles masts for the electric light have been erected, and now a number of lights from these high points light the city, the company having a contract with the municipal corporation. Engravings on this page show the form of the lamp, and also the appearance of the mast on which the light is placed.

In another column of this number of the PRESS (page 322) we give the detail of the use of the lift in Los Angeles, where it has given great satisfaction, and displaced the gas for street lighting. It is probable that other cities on this coast will adopt the system of electric lighting when the advantageous results become more widely known.

The Mechanics' Fair.

It was supposed by some that the usual annual fair of the Mechanics' Institute would be omitted this year, owing to the use of the building by the Triennial Conclave. This is not so, however, as the fair will be held as usual. The only change is a postponement of the exhibition to a later date than has usually been the case. It will open September 11th, and close on October 13th. A meeting of the Board of Trustees of the Mechanics' Institute was held on Tuesday evening, when an organization was effected of the Board of Managers of the Eighteenth Industrial Exhibition. It was decided to give premiums, a list of which will be issued as soon as possible, and sent with circulars to Pacific coast manufacturers, all former exhibitors, and to those who will be likely to have products to show.

As we are growing in manufactures, it is to be hoped that the fair will excel all previous ones in this connection. There is no reason why a very creditable exhibition cannot be made, if those for whose interest the fair is arranged, will cooperate with the managers by coming forward promptly with their exhibits. The Board of managers for this fair is as follows: P. B. Cornwall, President; A. W. Starbird, vice President; J. A. Bauer, Treasurer; B. Jackson, C. Waterhouse, D. A. MacDonald, J. Pendergast, James Spiers, David Kerr, C. F. Bassett, J. R. Wilcox, Geo. H. Hopps, E. Fretwell, Geo. Spaulding. Although the officers are not yet appointed, it is probable that J. H. Culver will be Secretary, and J. H. Gilmore, Superintendent.

A CORRESPONDENT of the Bodie Free Press advises miners to stay away from Mount Cory district, Nev., as there are none over there that can make a living. The Mount Cory mine only employs fifteen men.

Improved Lifting Apparatus.

Clarence Sanborn, of Sacramento, has just patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, a new lifting apparatus of that kind in which great power is necessary, and in which the apparatus is required to stand at any point where it may be left. An engraving of Mr. Sanborn's device is given on this page. It is a simple and effective arrangement, as may be seen. It consists of a pulley, over which the lifting chain passes,

Electric Light Mast in Los Angeles.

and upon the same shaft two gear wheels, so fixed that their teeth alternate, that is, the teeth of one wheel correspond with the spaces of the other. The pulley over which the actuating chain or rope passes is fixed to shaft, which has short crank arms formed upon it corresponding with the gear wheels and with the size of their teeth, so that when the shaft is rotated, the crank arms or pins engage the teeth of the gear wheels, one after the other, and thus advance the chain pulley. This device also forms a perfect lock when left at any point.

A is a frame of any suitable form and size on which the gear and pulley shaft B is supported, while below this the cranked driving shaft C is journaled. On the shaft B is fixed the chain pulley D, having its periphery formed so as to prevent the hoisting chain E from slipping. On the same shaft are fixed two gear wheels FF. They are placed side by side, with a small inter-

vening space. These gears stand so that the teeth of one stand opposite the spaces of the other.

The shaft C has formed in it two eccentric pins, or short crank arm G, which stand on opposite sides of the axis of the shaft. The throw of these pins is fixed by the distance between the teeth of the gear wheels with which they correspond, so that as the shaft is revolved the pins enter the spaces between the teeth alternately, and thus advance them and turn the shaft and hoisting chain pulley. The pins

The Brush Light.

Sanborn's Lifting Apparatus.

in their revolution pass over the points of the teeth and into the spaces between them, without slip or lost motion, and with the least possible friction. When allowed to stand, with a weight suspended from the chain, the pins will lie in the spaces between the teeth, so as to form a perfect lock, and prevent the shaft from turning back. On the end of the shaft, C, is fixed a pulley, H, which is usually a chain pulley with an endless chain, I, passing over it and depending to a point within easy reach of the operator. Guides, J, depend from the frame, and the chain passes through them, so the chain is kept on the pulley when moving rapidly. This little piece of mechanism, though simple, is very ingenious in design.

THE Russian annual gold product we have seen recently reported at 2,000 pounds, worth in the aggregate, \$24,000,000, of which Eastern Siberia supplied \$18,000,000.

Gold Mining in Venezuela.

There is very little known of the mines of Venezuela outside of that country, although some portions of the region are very rich. On the northeast side of the Orinoco river are good quartz and placer mines. But the region is not healthy, and there is more fever and ague than gold. At the Caratal mines there are some English and some American companies working, but the latter are most numerous. Philadelphia people have several claims working gold quartz. This is in the State of Guayana.

In other parts of Venezuela the diggings were worked out by the Spaniards 100 years ago; still there are places which can be worked now, by the hydraulic system. Most of the placer work there is done by ground sluicing. Don Gonzales Guinan, of Valencia, State of Caribago, has the best mine they have opened. Some parts of his mine were worked out. On some parts of the claim there are big trees growing in the old excavations made by the former miners, but the ravines and gulches were the main sources of the wealth to these old miners. The small gulches, or *carradas*, are all thoroughly worked out.

Labor costs about eighty cents per day. There is plenty of water to run a hydraulic the year round, and a fine ditch has been made to bring it to the claim. The place belonging to Don Gonzales Guinan is called Mount Veruon. It is fifteen miles from Valencia. Mr. Guinan owns a league of land. They have by this time appliances for working the gravel beds by hydraulic process.

The old Spaniards, by following the rivers and searching the ravines discovered quantities of gold in the rivers Tesorero, Santa Cruz and Guaratarro, which abounded in large nuggets; the remains of their workings can be seen at the present day. The Caratal gold field is about 160 miles east southeast of Ciudad Bolivar, in Angostura, State of Guayana. It lies 100 miles south of the river Orinoco, some seventy-five miles up from the principal mouth.

When the dry season commences the rivers and streams sink rapidly; many dry up entirely; others still have a few water holes left. Then banks of sand and gravel are left high and dry, or partially so. On digging through these a gold-bearing bed is often met with, which furnishes nuggets and small grains of gold on washing.

CHEAP MILLING.—In commenting on an article in the MINING AND SCIENTIFIC PRESS of the 28th ult., in which the expense of milling ore in Southern Arizona is mentioned, the Prescott Courier says: "In our opinion it is this cheap milling of ore that has conducted so largely to the great prosperity of the southern portions of the territory, and this cheap milling is the result of care, forethought and the adoption of all labor-saving devices which have been discovered in practical metallurgy within the past few years. What the results will be in our own section, when the same careful and intelligent ways are brought into use in our mining camps, we leave it to our readers to imagine. A camp that has solved the problem of reducing silver ores at a cost of less than five dollars per ton, can have no fears for the future if it has mines deserving of the name."

THE pay rolls of the Ophir, Mexican, Union Consolidated and Sierra Nevada for the month of April, says the *Territorial Enterprise*, aggregate \$28,518; California, Consolidated Virginia and C. and C. shaft, \$15,170; Union shaft, \$10,856; Utah, \$4,253, making a total of \$58,797 for the six mines mentioned.

The Soils of California.*

A General Review of the Quality of Our Agricultural Lands

While it would be impossible to give, in any brief space, a detailed account of the great variety of soils occurring within the wide area of the State of California, only a few of which have as yet received any close examination, some general statements may be made to show the high value of some of the apparently most arid lands, when subjected to the life-giving influence of irrigation.

As regards, first, the great valley, the two climatic divisions defined above are maintained also, measurably, as concerns the soils. Broadly speaking, it may be said that in the northern division (the Sacramento valley) the soils are prevalently loams, more or less heavy, largely interspersed with tracts of heavy clay or "adobe" soils, often the exact counterpart of the "prairie" soils of the Mississippi valley; while in the southern portion, or San Joaquin valley, the bulk of the soil is altogether prevalently sandy, occasionally to the extent of rendering them sterile; and what is there called "adobe," by way of contrast, would mostly be elsewhere considered a moderately clayey loam. As to intrinsic fertility, it would be difficult to decide between the two divisions; for while the heavier soils, other things being equal, are usually the richer in plant food, and therefore the more durable; the great depth of the light soils of the San Joaquin valley seems to compensate in a measure for the somewhat inferior percentage of plant food. This is the more true, as the "sand" is, to a considerable extent, not simply siliceous, but consists largely of comminuted gigantic and eruptive rocks, with an admixture of the ancient slates, or rather schists, which cover the flanks of the Sierra and constitute the proverbial "bed rock." Moreover, the "foothills" are commonly bordered, on the valley side, by a rolling plateau land, underlain by the marly strata of the tertiary formation, and these, commingling with the materials brought from the higher lands, form naturally marled soils, whose thriftiness, when under irrigation, contrasts strikingly with their barren aspect during all but the winter and early spring months, so long as they remain in their natural condition.

From Redding, at the head of the Sacramento valley, to Bakersfield, at that of the San Joaquin, the valley has along its eastern border a belt of upland, varying in width from one to twenty miles, and from twenty to fifty feet above the natural drainage level, the soil of which is a yellow or reddish loam of varying character, evidently formed by the intermixture of the red soil of the foothills with the valley deposits. Much of this land, which is mostly too high to be reached by the present irrigation canal, has a singular hillocky surface, known as "hog wallows," doubtless the results of aqueous erosion in past periods. These "hog wallow" lands differ essentially both in their character and origin from those similarly named in Texas and other Gulf States (which are mostly heavy prairie soils), and even as far south as Merced county produce excellent cereal crops, as well as fruits, without irrigation.

On the western, or Coast Range side of the valley, the soils are usually materially different. The Coast Range consists in the main of gray tertiary and cretaceous materials, prevalently clayey northward of San Francisco bay, but growing more and more sandy, on the whole, in a southward direction. Hence, we find extensive tracts of very stiff "adobe," all of very variable degrees of fertility, on the western side of the Sacramento valley, and as far south as the southern line of San Joaquin county, where the widely gaping cracks of the adobe, during the dry season, attract the attention of even the casual passer-by. Southward, the soils lying at the foot of the Coast Range become increasingly sandy, as do the bordering hills, until, in the region opposite Tulare lake, it is reported to be a "sandy desert." This statement may require to be taken with a considerable grain of allowance, since in the absence of any opportunity for irrigation, and of any serious attempts at settlement thus far, the capabilities of the region can hardly be said to have been fairly tested.

The soils of the western border of the Sacramento valley are at many points materially and most beneficially modified by the admixture of materials contributed by the tributary valleys heading within the region of eruptive or volcanic rocks, whose southern portion has become noted for the high quality of the vines produced in the valleys of Sonoma and Napa. These soils are also originally red, as is still the case on the mountain sides and higher benches of the valleys, and while less suited to cereal culture, they seem to be pre-eminently adapted to the perfecting of the higher qualities of fruits.

The orchard products of Vacaville, widely known for their excellence, are grown on such soils, and the fruit growing region of Solano and Yolo counties, the present center of the raisin industry, is covered by the joint deposits of the Sacramento river and Putah creek, the latter one of the main drains of the volcanic region.

Soils quite similar to these, both in origin and productive qualities, exist on the opposite side of the valley, where the Tuolumne, Mokelumne and Cosumnes rivers traverse the volcanic tuffs that cover the gold-bearing gravels of

Table Mountain. As regards their general chemical character, the soils of the entire valley (of which quite a number have been analyzed, partly under the direction of the State Agricultural College, partly under those of the Census Office), are throughout remarkable for a high percentage of lime, which rarely falls below four tenths of one per cent, and most commonly ranges from one half to one and a quarter per cent. This circumstance explains, in a measure, the high thriftiness of these soils, allowing the rapid development and generous fruiting which accompanies the minimum allowance of moisture, and maintains the farmer's hopes, that the success of a single season will suffice to wipe out the financial failures of two or three dry seasons. A generous allowance of potash accompanies the lime, even in the very sandy soils of the Tulare plains, mostly exceeding four tenths, and ranging as high as one and a quarter per cent. The phosphates are on the whole low in the sandier soils of the San Joaquin Valley, but high in the adobe soils of both divisions.

The red soils of the foothills have already been mentioned. The character of the foothills of the Sierra Nevada throughout its course along the great valley, varying from a moderately clayey loam (as in the placer region of El Dorado and Placer counties) to a heavy, though not uncommonly gravelly, is an orange-red clay. This character seems to be sensibly the same, whether the soil be derived from the decomposition of the ancient slate "bed rock" or directly from the granite rocks, thus creating a presumption that the two rocks are closely related.

Where the foothill soils either obtain a sufficiency of moisture naturally, or can be irrigated, they prove abundantly productive, and are rapidly acquiring a special reputation for the excellence of their fruit product, both of orchards and vineyards. While at present it is in the main a region of spring pastures, it is doubtless destined to be in the future one of small farms, producing products of high value. The soils are highly charged with iron (ferrie hydrate or rust) to the extent of from seven to over twelve per cent; which, being finely divided, imparts to them the intense orange-red tint so familiar in the region of the placer mines, and during the dry season manifesting itself in the equally familiar red dust that disguises the natural tints even on the trees themselves. The soils of the foothills, so far as have been analyzed, agree with the soils of the valley in having a high percentage of lime, from about one third to one and a half per cent, while the supply of potash and phosphates, as well as of organic matter, is smaller, and sometimes low, though never apparently inadequate for present productiveness, in the presence of so much lime.

The soils of the Coast Range, vary greatly in the different portions of that broad belt of hilly land. In the middle portion, more or less directly related to the bay of San Francisco, the "adobe" character is prevalent, not only in the valleys, but even on the summits of its rounded ridges, where, in favorable seasons, the yields of grain may be as high as in the valleys themselves. The soil is usually many feet in depth, with only here and there a rocky knoll projecting through it; cracks wide open in summer, and when the rains come somewhat abruptly and violently, the water, descending quickly to the underlying bedrock, gives rise to innumerable land slides, sometimes of considerable extent, and of vital importance to land owners.

In the valleys intersecting such regions, notably along the border of San Francisco bay, there lie highly fertile tracts of black adobe, or black prairie soil, sometimes so stiff and waxy as to be difficult to till, but under good treatment and in favorable seasons, profusely productive. The adobe tracts are intersected at right angles to the bay by the belts of lighter sediment brought down by the present streams.

In the country lying northward of the bay, the soils formed by the eruptive and volcanic rocks assume increased importance, and constitute the leading features of the grape-growing region of Sonoma, Napa, Solano and Yolo counties, as well as, farther north, in Lake and adjoining portions of Colusa and Mendocino. Here the lower portions of the mountain sides are frequently constituted of the heavy tertiary and cretaceous materials which form adobe, while the upper portion consists of igneous rocks yielding lighter soils, often deeply colored with iron, and more especially adapted to fruit culture. The valley soils are, of course, a mixture of both, and it is on such composite soils that the enormous yields of from 12 to 14 tons of grapes per acre are sometimes obtained.

Of the soils of the mountainous regions of Mendocino and the country northward to the Oregon line, but few data have thus far been obtained. Specimens of valley soils, and especially of that of the El River, in Humboldt county, seem to show a great similarity to those of the coast valleys south of San Francisco bay. It is a gray silt with very little coarse sand, many feet in depth, with high percentage of potash and phosphates, but deficient in lime, and probably from that cause difficult to till, and somewhat unthrifty after continued cultivation. Southward of San Francisco bay, where with otherwise similar composition the lime percentage is large, this inconvenience is not observed, and these silty valley soils are remarkable for their retention of moisture near the surface throughout the dry season—a highly valuable property in the dry climate. Adobe soils are exceptional in the southern Coast Range region, gray loams or silts, or sometimes sandy soils,

being on the whole predominant in the uplands also. In the semi-tropic region of Los Angeles, San Bernardino and San Diego, the uplands or mesas which occupy the larger portion of the surface have usually a reddish, gravelly loam soil, more or less heavy in different localities, but on the whole remarkably uniform in its character. It seems to be a modification of the foothills soil northward of the Sierra San Fernando, but of greater depth, more easily tilled, and with higher percentage of plant food, especially of phosphates. Hence, though of the desolately arid aspect of a gravel bed in the dry season, these mesa lands when irrigated prove profusely fertile, and in spring are covered with a dense carpet of bright flowers. For fruits adapted to the climate, they are probably excelled by few so far as quality is concerned; although, on account of greater facility for irrigation, the lower levels and the terraces or benches along the streams have chiefly been occupied.

The soils of the Colorado River bottom is a light, pale-colored loam of great depth, highly calcareous, with over one per cent of potash, but a comparatively low amount of phosphates for a river bottom. It proves extremely fertile where cultivated.

The soils of the Mojave and Colorado deserts have received but little attention and examination thus far. While a portion of the surface is covered simply with drifting sand underlain by rock or hard pan, there are in the Mojave desert, at least, extensive tracts possessing a soil of fine gray silt, on which the yucca tree attains a luxuriant development; while others are covered with low but dense growth of hardy shrubs, and grass enough to render the spring pasture valuable and nutritious, while the sheep crop the leaves of shrubs later in the season. Plainly, a large portion of this desolate-looking country evidently reawaits only the life-giving influence of water to be at least available for stock-raising, and to no inconsiderable extent for cultivation also. The lower portions of the Colorado desert especially are so severely afflicted with alkali of a corrosive character that, being incapable of drainage on account of being below the sea level, their reclamation seems hopeless.

The Electric Light in Los Angeles.

The "Pueblo," now city of Los Angeles, has an area of six miles square, or thirty-six square miles. It has a population, now estimated, of 22,000, being an increase of 10,000 since 1880. It has been lighted with gas for about fifteen years, at an expense varying from \$3,000 to \$10,000 per annum. But the area of gas lighting comprised only a few of the main streets, less than two miles in length and a half mile in width, or one thirty-sixth of its area.

Last summer a proposition was made to supply the city with electric light (under the Brush patent), by means of masts, the lamps to be suspended at the top. By such method a large area can be illuminated, and not only the streets and alleys, but yards, areas and open spaces are lighted. This system is peculiarly adapted to towns where there are few high buildings or narrow streets, and a larger territory can be furnished with light than if placed on posts, and at a less cost than other methods. The electric company proposed to furnish seven masts, of 150 feet high from the ground, at which elevation there were to be placed on each mast three electric light are-lamps, of 3,000 candle power each. The price was \$1,000 per annum, each mast, or a total of \$7,000.

It was intended by the contractor that these masts should be placed within the space occupied by the gas lamps then burning. The gas company put in a bid for 165 lamps at \$6.85, or fifteen dollars less than the electric light bid. After a long consideration and much hesitancy, the council approved and adopted the electric light by a unanimous vote. In placing the masts, against the wishes of the contractor who wished them placed within the usual area of gas lighting (in order that the superiority over gas might be more apparent), all the masts, save two, were located outside the old area of gas lighting, and in two instances a mile beyond.

Taking the distance from the center mast on Main and Commercial, the mast in East Los Angeles is two miles, Boyle lights one and one third miles, Main and Sixth four fifths of a mile, First and Vine one half mile, First and Olive one half mile, Normal School hill four fifths of a mile, or comprising an area of nearly three miles long and one and one half miles wide, an inside area of four and one half square miles, as against the gas area of one mile. But as the masts throw a practicable light nearly a mile distant, the area lighted is more than ten square miles by electric light—over one square mile by gas at the same price.

Notwithstanding the immense area the masts were forced to supply, it is stated that the whole area of the city is practically lighted, and those portions in the vicinity of the masts very brilliantly—for at a distance of a quarter to a third of a mile from a mast one can perceive the time on the dial of a watch.

The light is particularly effective on wet, cloudy or foggy nights. The light seeming at such times to have more power than on clear nights, and it is a common saying that they "are the most effective, when needed the most." We are told that the lights have given general satisfaction to the citizens.

The lights were turned on the first of January, 1883, and after a test the City Council or-

dered every gas street-lamp discontinued, and the city is wholly lighted by electricity. The lamps are suspended on cages: these cages are lowered for trimming to the cross-trees. The masts are made of spars from Puget Sound. They are of two pieces being at about twenty inches in diameter at the ground and tapering to six inches at the top. They are very graceful and beautiful, and without a knot the whole distance. The light is turned on instantaneously over the whole city.

Among the many advantages of the mast system is the economy, as it would cost from five to ten times as much to light the same area with gas. There should be taken into consideration also its efficiency in "policing" the city, chief of police testifying that it aids the police wonderfully in watching and guarding against the criminal element.

Real estate, outside of old area of gas-lighting, has appreciated in value from benefits of the light. It is not an uncommon remark by residents in such localities, that they would be willing to pay an extra tax if needed rather than dispense with electric light and return to gas, but as it costs less no tax is needed.

Of over fifty letters addressed to the city officials and to prominent citizens, every one returned an emphatic endorsement to the efficiency of the electric lights, and their superiority over gas light. The press is equally emphatic. The *Herald* April 28th, in an editorial referring to the proposition to light San Francisco with electric light, says: "Under our system of electric illumination, the city proper is far more satisfactorily lighted than ever before, while the benefits to the people residing in the suburbs are simply incalculable. Though the masts placed at the head of First street, and near the Normal school, the illumination is so vivid that the Rev. Mr. Bovard, the Principal of the University of Southern California, can see to put up his horse evenings, though at a distance of three miles. We see by Tuesday's *Bulletin* that the California Electric Light Company has made a proposition to the Board of Supervisors in San Francisco to supply a section of that city with 200 Brush electric lamps, of an aggregate of 420,000 candle power, as against the present service of 1,700 street gas lamps of 27,900 candle power, and at a considerable saving in outlay at that. While the *Herald* does not presume to dictate to the municipal legislators of our metropolitan city, we think they will be very wise indeed to add to the illumination of San Francisco, while, at the same time, they curtail the expense of their illuminating service. As a chandelier over-shadows a farthing rush light, so do the Brush electric lamps douse the faint glimmer of the feeble and flickering street gas lamps of the old days. We have seen the contrast, and we speak advisedly."

The *Times* editorially says: "San Francisco has been in darkness for some time, so far as street lights have been concerned. From private sources it is learned that there is a sentiment largely in favor of the electric light, which will give a much better light for a great deal less money. The people of Los Angeles feel rich in having the light. Her streets are lighted as they never were before. More than four times the extent of territory is now lighted than under the old regime, and for about the same cost. There is no more growling and grumbling over the lighting of the streets, which used to form an ever ringing chorus. There is still a need of more masts, but the present system gives eminent satisfaction. A peculiarity of this light—and this feature is particularly dwelt upon by most of those who have expressed their opinion—is, that it shows to better advantage in wet or foggy weather than in bright clear weather. The darker or more foggy the weather, the better the light. In fact, it shines out strongest when most needed. The light can be especially recommended for San Francisco and other places on the bay where fogs are frequent."

The *Express* also concurs editorially as follows: "There is no place on the coast where the new light has been so thoroughly tested as in Los Angeles, and after several months the general verdict is in favor of electricity as the cheapest and most effective way of illumination yet found. If there are any of our citizens who differ from this view, we have not met them. There are seven masts in this city, costing \$1,000 each per year. These masts are so distributed that a large area of the town is lighted. From the masts on the higher grounds the light is cast to a distance of three miles with sufficient power to enable persons to dispense with lanterns in doing little chores around the home premises. This power of penetration causes the lights from all the masts to intermingle and overlap so that there is great evenness in the way the several parts of the city are lighted. So brilliant is the illumination even at considerable distances from the masts that windows where persons sleep require to be well curtained to shut out the rays. The same area could not be so well lighted by gas for four times the cost. Were the matter put to a popular vote in this city to-day the question as between gas and electric lights would be decided in favor of the latter by an overwhelming majority. The light is a success with us in every sense of the word."

EXTENSIVE mica beds are being found in Custer county, Dakota, of unsurpassed purity. This has become a large business, which is gradually assuming mammoth proportions. The demand for mica is increasing in proportion to any possible increase in the production. This branch of our mining industry is destined to become a very important one in the near future.

*From a report on the "Climatic and Agricultural Features of the Agricultural Lands of the Pacific Coast," by Prof. E. W. Hilgard.

MECHANICAL PROGRESS.

Hardening Taps and Dies.

A writer in the *Chicago Journal of Commerce* gives his experience in tempering as follows: The great difficulty in hardening tools is principally their liability to twist or get out of true; second, cracking (especially if large) after hardening; thirdly, getting the right temper. In our factory we use a great number of small taps and rimers; some of the rimers are nine inches long and a quarter of an inch in diameter; these we harden very successfully, not more than one out of a dozen being out of true. Our plan is as follows: First, carefully select your steel; let it be of the best cast, with a medium grain (a fine grained steel will break when much less force is applied than a coarser grained, and, although it will take a keener edge, it will not resist the strain required by a tap or rimer). Next center it, and turn off the scale and soften. The object of softening after the scale is removed, is to make the grain of the steel equal throughout; if it be softened with the scale on, it will generally cast. To soften, inclose the articles in a piece of gas tube, filling up with wrought iron turnings and plugging the ends with clay, making the whole red hot and allowing it to cool very slowly—i. e., leaving it in red hot ashes all night. This method makes the steel very soft, and equalizes the grain. After softening turn up the work, taking care not to bend it or straighten it, should it have cast, as it probably will in the process of softening. The reason for this is that, if the steel be bent or hammered, the grain will be closer in one place than another, and heat has a great tendency to bring it back to its original position. The next thing after finishing your tool is to harden it; first, slightly heat it over a gas or other flame, and rub it all over with a mixture of Castile soap and lampblack. This is to prevent the edges from being burnt. The next is to get a thick iron paper (the size we use is two inches diameter and three-fourths bore). This is well filled up with taps or rimers and charcoal dust, the ends being closed with clay as before. This is placed in the furnace and occasionally turned, until it is one uniform heat of cherry red, or on the outside a trifle hotter. It is then carefully removed from the fire, one end of the clay knocked off, and the contents allowed to drop perpendicularly into a solution of water, chloride of sodium and nitrate of iron; this is kept at a temperature of sixty degrees. The articles hardened should remain at least a quarter of an hour before being removed. This method of hardening may be summed up thus: Make the steel of one grain throughout, prevent it from oxidizing while being heated, allow every part to heat at the same time, avoid bending while hot, and lastly restore, if possible, by adding to the loss of carbon caused by heating. As I have taken up already too much of your valuable space, I will defer the method of tempering to some future time.

American Heavy Steel Forgings.

General Benet, Chief of Ordnance of the United States Army, has addressed a circular to a number of steel manufacturers of the United States, inquiring regarding their facilities for making the steel parts, of a certain specified quality, for the manufacture of the guns and mortars provided by the act of 1883 for the armament of fortifications. While there is no doubt that the quality required can be produced in this country, it may be questionable if forgings of the size required can be made, though this we cannot state positively, as we are not at present advised as to what the size, weight and shape of the pieces required are. The chief trouble appears to be that we have but very few hammers in this country that are heavy enough to forge the pieces that will be required. Some few, as Park, Bro. & Co., in Pittsburgh, and one or two other mills, are large enough. The Ordnance Department intends to make every effort to procure all the steel parts for guns, etc., from manufacturers in this country, if possible, and, with that end in view, will lend all proper encouragement and assistance to the firm, or firms, enterprising enough to take the matter in hand. Even if at the present time the heavier forgings cannot be obtained here, it is believed that at least steel hoops can be procured from some one of the many extensive tire rolling mills by a moderate outlay for the change of existing machinery.

PAPER RAILS AND CAR WHEELS.—In reply to a query in regard to an item in our issue of March 17, on paper rails, our correspondent will notice that the article was copied from and credited to the *Boston Journal of Commerce*, to which paper we refer him for the information he desires. Paper car wheels, so called, are far from being made exclusively of paper—such a wheel, however firmly made, would not carry a car fifty miles. What is called a "paper car wheel" is a paper center, with a steel tire. The "Allen paper car wheel" does remarkable service, but the wear all comes upon the steel tires. The paper centers to which they are bolted diminish the jarring by their elasticity, and are practically indestructible, because there is no wear on them, and they cannot be fractured like metal. Paper tires are absurd, and notwithstanding the endorsement of the *Boston Journal of Commerce* we believe that paper rails which somebody has said have been made and are to be put to actual use, are equally absurd.

The Brickwork of Chimneys, Etc.

In a communication to the *Deutsche Bauzeitung*, Herr Eckhartz has expressed his opinion that the cause of crevices being formed in the brickwork of chimneys, is the difference of temperature between the inner and outer surface. While in many cases in an ordinary factory chimney the mantel has internally a temperature of nearly 600° F., the external temperature is only about 60° on an average, the difference of expansion which is thus occasioned producing the cracks referred to. He dwells upon the use of iron hooping, and remarks that its object and result are not, strictly speaking, the prevention of expansion, but rather the attaining in the outer brickwork of a uniform distribution of the tension, and the prevention of concentration at certain points. The question whether wrought-iron rings in the inside of a mantel are liable by their own expansion to produce cracks has been for some time under discussion in German technical circles. A short time ago, Doctor Tomei recorded, in the journal above referred to, his opinion that the binding of chimneys by means of iron inside the masonry was a measure only to be recommended in exceptional cases, and with the observance of special care in its execution. He considered that the external binding of brickwork was, however, a question which was to be regarded in a different light. Herr Eckhartz, though not founding his remarks exactly on those of Dr. Tomei, further illustrates them by saying that if ironwork placed internally fails to prevent cracks, and even produces them, its employment in that way is not only superfluous, but injurious. If rightly constructed, he considers that for resisting the effects of the wind no hooping is required by a chimney. In further elucidation of the theory that internal hooping is unsuitable, he remarks that the ironwork should, as a matter of course, not be exposed to a high temperature; and he maintains that all rings inside masonry must, under these circumstances, be subjected to the influence of heat. If they have not sufficient space for their expansion they exercise a pressure upon the external brickwork, and thereby produce cracks. From the facts thus noted, Herr Eckhartz deduces the recommendation that in order to provide against the results of the difference in temperature to which allusion has been made, double walls should be constructed.

Steel Castings.

M. S. Kern, St. Petersburg, writes as follows on this subject: The process of manufacturing steel castings is very carefully kept secret at all works engaged in such a business throughout Europe. We have had several very interesting papers by M. Poullet, of Terrenoire, France, but he gives nearly nothing about the *modus operandi*. We understood well that a man is not expected to say everything about his method if it brings him pounds, shillings and pence. In Russia, very few steel castings were made at some works, and these may be called only experimental. We have lately received some information of a process of molding for steel castings, the invention of Mr. George Cowing. Quartz from Finland (a very pure specimen) was calcined, ground to rather fine powder, and mixed with from two to three per cent of glue, water and flour. This was used for molding. As a facing, fine quartz powder, with a small quantity of graphite well mixed with water, was used. The steel was prepared as follows: Eighty pounds of good iron, containing about .10 per cent of carbon (we propose to use soft basic steel) was melted in a crucible, and there were next added two pounds of silicon pig iron, containing 6.5 per cent of silicon and .5 pound of ferro-manganese, containing seventy-five per cent of manganese. The metal was kept in the furnace with the alloy for about fifteen minutes, and it was next poured into the molds. The castings had a very clean surface and were good. My opinion is that the clean surface depends much upon the molding material. There is certainly a reaction between the silica and the gases, and at the same time compresses the casting.

HIGH STEAM PRESSURE.—The economical advantage in the use of high steam pressures in steam engines results from two causes, independent of expansion. One, the minor cause, is that the potential energy of a given weight of steam is somewhat, though only slightly greater, at high pressures, compared with the heat required to produce such potential energy, than with low pressures. This is, however, only a trifling advantage, and not of the importance which is sometimes attached to it. The second cause, that the back pressure decreases relatively to the initial steam pressure as the latter is increased, the former remaining almost a constant within great ranges of initial steam pressure, is an important consideration in the use and economy of high steam pressure in engines. The resistance remaining in any special engine, almost a constant unit per square inch of piston area, the increase of initial steam pressure per square inch of piston area causes much loss from back pressure to be less as the size of cylinder decreases for the development of a given horse power. Independent of the expansion of steam at all, increase of steam pressure is synonymous with decrease of size of engine for the development of a given horse power.

SCIENTIFIC PROGRESS.

Notable Observations on Solar Radiation.

Prof. S. P. Langley, of the Allegheny Observatory, who made a scientific expedition to Mount Whitney, in Southern California, in 1881, to determine chiefly the value of the solar constant (that is the amount of heat the sun sends to the earth), and other related subjects, has been led incidentally to a number of curious and important conclusions respecting the influence of the atmosphere on the sun's rays. The observers noticed, as they ascended the mountain and the air grew colder, the sun's heat became progressively more intense, until their faces and hands, already browned by weeks of exposure, were burned anew, and far more in the cold than in the desert heat. When they had reached an elevation at which the surface temperature of the soil fell to the freezing point, the solar radiation became so intense that many of the party presented the appearance of having been burned by an actual fire; and near the summit the temperature in a copper vessel, over which were laid two sheets of plain window glass, rose above the boiling point, and "it was certain that we could boil water by the direct solar rays in such a vessel among the snow fields."

From this experience, the conclusion was justified that, were it not for the agency of the air in absorbing, storing and distributing the solar rays, the temperature of the earth's surface would fall very greatly, even though it received a much larger quantity of radiant heat from the sun. Prof. Langley expresses the opinion that without an atmosphere, the earth's temperature would fall fifty degrees below zero (Fahr.).

These observations also lead to other interesting inferences. "We see," says Prof. Langley, "if these results be true, that the temperature of a planet may, and not improbably does, depend far less upon its neighborhood or to remoteness from the sun, than upon the constitution of its gaseous envelope; and, indeed, it is hardly too much to say that we might approximately indicate the constitution of an atmosphere which would make Mercury a colder planet than the earth, or Neptune as warm and habitable a one."

THE PHOSPHORESCENT FLAME OF SULPHUR.

According to a German scientific journal, Herr Hennemann, having raised the question whether phosphorus among the metalloids was the only one which underwent slow combustion at a low temperature, becoming luminous, has answered it satisfactorily by experiment. He found that sulphur shows this phenomenon very well, though at a temperature higher than is required for phosphorus. If a heated rod of glass be dipped in pulverized sulphur, it becomes covered with the fused material which takes fire. If now the flame be blown out, the sulphur still continues to burn, but with a whitish flame visible distinctly only in the dark. The white phosphorescent light is seen much better when the sulphur is heated rapidly to 180° on a plate in the interior of a metallic air bath. White flames from three to four inches long flicker through the box, and by properly regulating the heat this slow combustion may be continued for an hour without the appearance of the blue flame. Various kinds of sulphur were tried, but in each case with the same result. Many compounds of sulphur act in the same way; thus cinnamon, antimonious sulphide, arsenious sulphide and others all show the white flame. The odor emitted when the sulphur thus burns is peculiar, recalling that of hydrogen persulphide, camphor and ozone, and is the odor generally ascribed to sulphur vapors.

PHOTOGRAPHING SOUND WAVES. Some interesting experiments relating to the photography of sound vibrations were recently made by the well known German chemist, Professor Boltzman. According to the method devised by him, a small thin platinum plate was fixed perpendicularly to the center of a thin iron tympanum like that of a telephone. Another platinum plate was fixed near the first so as to form a fine slit between them, and this slit was brought into the focus of a collecting lens upon which sunlight fell. After passing through the slit, the rays went to a selenium cell, which, with two telephones, was in circuit with twelve Leclanche cells. Single sounds spoken to the tympanum could be heard. When the rays, after traversing the slit, which varied in width with the vibrations, were rendered parallel and concentrated by a lens upon the selenium cell, the apparatus could be employed as a photophone. Intense sunlight concentrated upon the platinum plate by means of a solar microscope, and an image of the shadow of the platinum plate thrown upon a glass plate prepared with Vogel's emulsion, gave a photograph of the sound vibrations when the prepared plate was rapidly moved in a direction perpendicular to the line of light. It appears that for the vowel sounds the curves produced were simple, while those of the consonants were complex, those for *t, m, n, c, p* and *k* resembling the curves formed by König for "e" by his sound flames.

A new kind of alum, under the name of double alum, has been introduced in the German trade. It is a transparent sulphate of alumina, but has a larger proportion of the latter than usual, and is free from iron and acids.

FREEZING OF LIQUIDS IN LIVING VEGETABLE TISSUE. As is well known, there is a prevalent opinion that the liquid in vegetable tissues congeals as ordinary liquids do, and, expanding, often causes trees to burst with an explosive sound. Experiments on young and vigorous trees varying from 1 foot to 3 feet in diameter, demonstrated that in no instance was there the slightest tendency to expand. In the case of a maple, 3 feet 11 inches in circumference, there appeared to be a contraction of $\frac{1}{2}$ inch. In dead wood soaked with water there was an evident expansion, and the cleavage with explosion, noted in the case of forest trees in high northern regions, may result from the freezing of liquid in the center or less vital parts of the trunks. In some hardy succulents, however, instead of expansion under frost, there was a marked contraction. The joints or sections of stems in many species shrink remarkably with the lowering of the temperature, so that the whole surface in winter is very much wrinkled. Assuming as a fact that the liquids in plant which are known to endure frost without injury did not congeal, it might be a question as to what power enabled this successful resistance. It was probably a vital power, for the sap of plants, after it was drawn from them, congealed easily. In the large maple tree already referred to, the juices not solidified in the tree exuded from the wounded portion and then froze, hanging from the trees as icicles, often six inches long.

AN ARTIFICIAL AURORA. A telegram has been received by the Finnish Academy of Sciences from Professor S. Lemström, chief of the Finnish Meteorological Observatory at Sodankylä. He states that having placed a galvanic battery with conductors, covering an area of 900 square metres, on the hill of Oatunturi, he found the cone to be generally surrounded by a halo, yellow-white in color, which faintly but perfectly yields the spectrum of the aurora borealis. This, he states, furnishes a direct proof of the electrical nature of the aurora, and opens a new field in the study of the physical condition of the earth. A further telegram has been received, in which Professor Lemström states that experiment, with the aurora borealis made December 29, in Enare, near Kaitaka, on the hill of Pietarinturi, confirm the results of those at Oatunturi. On that date a straight beam of aurora was seen over the galvanic apparatus. It also appears from the magnetic observations that the terrestrial current ceases below the aurora, while the atmospheric current rapidly increases, but depends on the area of the galvanic apparatus, to which it seems to be proportional. The Professor regrets that with the means at his disposal further experiments cannot be made, and that he intended almost immediately to withdraw the apparatus.

A NEW METHOD OF DETERMINING THE GRAVITY OF SOLIDS. Prof. Munroe having occasion to ascertain on shipboard the specific gravities of samples of coal, and being prevented by the motion of the vessel from using the balance, devised a procedure which not merely served his purpose, but is susceptible of wide application. Placing a block of coal in a liquid so dense as to float it, he gradually reduced the density by the admixture of a lighter liquid, until the coal floated immersed. The homogeneity of the mixture being maintained by stirring, this equilibrium was, of course, reached only when the specific gravity of the liquid became equal to that of the immersed solid. He then measured the specific gravity of the liquid with a common hydrometer. For the location of the lighter solids he used a thick solution of cane sugar; for anthracite, strong sulphuric acid. As a test of the accuracy of the results, he afterward repeated the determinations by the usual methods, with but smallest fractions of difference.

INFLUENCE OF ANIMALS IN PREVENTING OR CONTROLLING FOREST GROWTH. A correspondent, writing from Johnstonville, S. C., incidentally mentions a curious instance of the influence of animals in controlling or preventing forest growths. It appears that the fondness of hogs for the juicy roots of young pines leads them to seek them assiduously, so that where hogs are allowed to roam in that region one can hardly find a young long leafed pine in a thousand acres of pine forest. There being no young trees to take the place of the old ones used up by the lumbermen and the porcine marauders, this species of pine is disappearing.

GALVANI ANTICIPATED.—Prof. S. Thompson, according to the *Journal of Science*, has pointed out the little-known fact that Swammerdam anticipated the famous initial experiment of Galvani by more than 100 years. Being on a visit in Tuscany in 1678, the illustrious Dutch naturalist showed to the Grand Duke that when a portion of the muscle of a frog's leg, hanging by a thread of nerve, bound with copper wire, was held over a copper support, so that both nerve and wire touch the copper, the muscle is at once contracted.

THE ELECTRICAL RESISTANCE OF TEMPERED GLASS. Some interesting experiments concerning the above subject were recently made by M. G. Foussereau, showing that the electrical resistance of glass diminishes considerably on being tempered. On the other hand, annealing tempered glass was found to restore its higher resistance. The same may be said of tempered crystal. The resistance of glass, tempered or untempered, provided the glass is not unduly heated, is found to remain constant.

up and worked. The water privilege of this mine is the best in the district, and would fully supply power the year round for any number of stamps that might be required.

San Bernardino.

CHALMER.—Calico Print, May 5: This promising claim, located not far south of the Silver Odessa, is owned by Messrs. J. H. McCutcheon and Dickinson. For over six months they have been prospecting and working the same. The indications have been good from the start. A tunnel was driven in 70 ft, but they have not yet struck the main ledge. There seem to be several ledges on the claim, from which assays have been taken that show well. The most encouraging prospect is seen in a shaft that is being sunk in the mouth of the tunnel, which is 15 ft deep and 35 ft from the surface to the bottom.

BORAX CLAIM. About half a mile east of the Garfield, Mrs. Townsend has two men at work on a claim called the Lady Blanch, from which they are taking borax and sending it.

LYON.—Messrs. Miller and McBride have several men at work on this claim, which is showing up well. A tunnel has been driven in on the east, and also one on the west side of the hill, and soon they will meet in the center of the ledge, when they will commence stoping.

SILVER ODESSA.—The work on this fine claim still progresses. The roar of the ore cars ascending and descending the chute, and the loud reports of blasts can be heard at the mine at all hours of the day. The average quantity of fine ore increases instead of diminishing. The work of tearing down the bluff continues. The ore lies in pockets. Sometimes they will be taking out ore from a place that is exceedingly rich, and again will strike a spot that contains only waste rock and very low grade ore; but the average quantity of good ore continues to increase, and no symptoms of its failing can be seen.

GOBLER.—The appearance of this claim has changed considerably. There are 16 men at work in two places on the east side of the mine. The bluff on the west side of the canyon is being blasted and cut away, opening large veins from which eight tons of good ore was taken daily to the mill. The whole bluff contains ore, and numerous veins have been opened; but there is a large vein, seemingly the principal one, running a long distance through the vein from northwest to southeast. It is several feet in width, and in some places spreads out into pockets from which considerable rich ore is taken.

OCCIDENTAL.—A large quantity of rich ore has been taken out, and an immense body laid bare in the cuts and tunnel. This mine is developing into a bonanza.

ORIENTAL.—Hoisting works have been put up on this well known mine, and every facility for getting out the ore is being made. The usual quantity of good ore is being taken out daily.

SILVER KING.—Work in all the levels of this principal mine of Calico is progressing in good shape. The ore bodies that have been penetrated are showing up better than ever. Nadeau's ore teams are still hauling ore to the Oro Grande mill which yields rich returns in bullion every week.

ALHAMBRA.—There are eight men at work making improvements, and when they are completed the mine will be in a condition to yield an immense quantity of ore. A large quantity of ore has already been taken out and milled by the former owners with most satisfactory results. John McBride is foreman of the mine.

Sierra.

A RICH STRIKE.—Sierra Tribune: A very favorable strike was made on what is known as the Page ledge, located in Sailor ravine, last week. J. Cowden, one of the owners, brought down samples of quartz that showed free gold in abundance, and reported that an ore body had been encountered that had every indication of proving permanent and rich.

A FINE PROSPECT.—The Bald Mountain Extension Co. encountered the channel on the South Fork ground at Forest City this week. Eighteen carloads of gravel taken out and washed paid \$2 per load. As was stated in these columns a couple of weeks ago, the South Fork mine has been leased by the former company. The Extension owners are quite jubilant over the early strike made, and express the belief that the course of the channel is proof positive that it will find its way into their ground eventually.

FOREST CITY.—Lumber is being delivered daily at Forest City from the various saw mills in that vicinity, for parties who will rebuild on the burned district. Quite a number of buildings are already under headway, and, in the course of three or four months, it is quite sure that no evidence of the great fire will remain. The recent developments in the Bald Mountain mine have given the people there new courage, and it is stated that the prospects for a prosperous season are flattering.

Shasta.

MAD OX.—Shasta Courier, May 7: The Mad Ox mill does good work with water power, but when the new steam machinery is placed in position the old Mad Ox hills will resound with the lively pounding of the stamps. We understand that the mine is turning out splendid ore, and lots of it. If old man Peckham, the locator of that mine, could have realized how rich it was he would not have sold out for \$4,000.

FROM FURNACEVILLE.—Cor. Redding Independent, May 3: The mines, outside of the Afterthought, in this district are doing but little work, though several claims are owned and represented here. The Afterthought has had several set-backs, such as storms, freshets and freezing, and the procuring of necessary supplies, and have therefore met with several detentions, and would have to shut down for a while; and then there is not the necessary number of pans, leachers, agitators, etc., to keep the stamps running all the time; but for all that a large amount of ore has been run through, and the bullion—copper and silver—is of very good appearance. Mr. Stewart, the superintendent, is well satisfied with the process, if he can keep all the stamps running, that he can soon make the mine pay dividends. Most of the ore now being taken from the mine looks well and assays well. Several shipments of silver and copper bricks, below, have made excellent returns, quite satisfactory to Mr. Stewart. There are employed in and about the mill and mine about 25 men, who receive their wages regularly; that, though,

has been a noted fact in the district, that the hands always have received their pay in full, although several failures have occurred in making the mines pay heretofore by different processes than the present one.

Tuolumne.

WASTING.—Tuolumne Independent, May 5: Charley Seaver is washing away the place in the rear of his residence at Springfield, and it pays well. In early days Springfield Flat and all about the town swarmed with miners who made large wages in washing the surface. Down among the boulders are many rich spots difficult to get at, but which will some day reward the lucky man who finds them.

NEVADA.

Washoe District.

HALE & NORROSS.—Enterprise, May 5: The north drift on the ore streaks has been discontinued at a distance of 78 ft from the main north drift, and a cross drift has been started east to a point under the winze, down from the 2400 level.

SIERRA NEVADA.—Good headway is making in the north lateral drift on the 2600 level. Some ore of a fair milling quality is being taken out of north drift No. 2 on the 2600. This streak appears to be the top of a body of ore which will be found to lie in the level below.

CHOLLAR.—The indications are that crosscut A, on the 2600 level, will find a considerable body of good ore. It has already cut a seam of some 15 inches in width of very fair ore, though it has yet a considerable distance to go to reach the point where it was expected that it would cut the ore streaks followed south 65 ft by the Hale & Norross.

UNION CON.—The winze chamber at the end of the joint Sierra Nevada crosscut on the 2600 level is completed, and the winze started for the 3100 level.

CON VIRGINIA.—On the 2500 level work has been discontinued in the face of the southeast drift in order to allow the hot water to drain out at the face. On the 2700 level drain boxes are being put in.

OHMER.—Good progress is making in cleaning out and repairing the old Central tunnel. A considerable amount of ore is being taken out at the croppings.

MEXICAN.—The joint Ophir east crosscut on the 3100 level is being extended at the rate of about 30 ft per week. It is now passing into softer or more favorable material.

UTAH.—The leak in the pipe in the drift passing through Sierra Nevada ground has been found and repaired. In order to reach the end of the drift without cleaning out its whole length a cross drift and upraise are now being made from the level below.

CALIFORNIA.—The C. & C. winze, which is to go to the 2900 level, is progressing well, and the south drift with which the winze will connect is being pushed ahead as rapidly as possible.

BEST & BELCHER.—The northeast drift on the 2505 level is cutting occasional streaks and bunches of quartz that give low assays. The ground is of very favorable appearance.

ANDES.—The north drift continues in quartz of a fine appearance, but it shows very little metal. The west drift from the raise is in better material.

ALTA.—Good progress is making in the drain drift, work being driven at both ends. The rock continues favorable, though somewhat hard.

Bernice District.

GOLDEN CROWN.—Silver State, May 2: A loveable correspondent, who has just returned from Bernice, writes as follows about the district: "The Golden Crown mine, owned by Wallace Goodell, is looking well, and there are several fine prospects in the vicinity of that mine. Hoyt & Gilbert have been opening up their mine lately and have a large quantity of good ore in sight. James Denney sold a half interest in his mine to Austin men, who are going to work to develop it immediately. G. W. Bothwell has quite a force of men at work erecting his mill, which is expected to be in running order about the 1st of July, by which time there will be ore enough on the dumps and in sight in the several mines to keep it running steadily. The people of Bernice suffer great inconvenience from lack of mail facilities, but they have hopes of getting a mail line established to the camp ere long."

Cherry Creek District.

MILL.—White Pine News, May 5: The whistle of the Exchange mill is now music to the ear. The Exchange people are putting through some good ore, and we learn they have quite a large amount of the same kind out and in sight.

Crabb District.

ORE.—Cor. Esmeralda Herald, May 3: The Plummer Bros. have run 9½ tons of ore from their mine through the mill at this place, which worked over \$20 per ton. They talk of hauling over 30 tons more that they have out and working it. The mill, it is expected, will start up on ore from the Eagle Bird mine about the middle of May. Plummer Bros. think the ore they have on the dump is better than what they worked.

Columbus District.

NORTHERN BELLE.—True Picture, May 5: There is a material improvement on the fourth shaft level, both in the stope and in the main drift. Some fine ore is being extracted from the winze below the second shaft level, and the stopes above the first shaft level are yielding as usual. There is quite an improvement in the eastern end of the ninth level, and some ore of excellent grade is being taken from that part of the mine. Everything in and about the mine is progressing in a satisfactory manner. Both mills are running steadily and doing good work. The Bullion shipments amounted to \$12,662.44 for the week ending May 3d, and to a total for the month of April of \$88,309.01.

MOUNT DIABLO.—The stope below the third level, near winze No. 4, is giving a little \$220 chloride. The intermediate stope, between the second and third levels, and nearly above winze No. 1, is yielding a small amount of \$200 ore. The stope from the east drift on the second level has given considerable \$70 ore. The stope above the west drift from the Callison winze is looking much the same as at the date of last report; the west end shows two feet of \$75 ore; the center of the stope shows 8 or 10 inches of \$80 ore. The west intermediate, below the first level, is turning out considerable \$70 ore. A bullion shipment was made on April 26th, amounting to

\$5,624.58, and another on the 30th valued at \$7,735.13. The total shipments on April account were \$91,200.08, and one of \$5,681.06 on May 3d.

Kinsley District.

COPPER.—Elko Independent, May 5: Gen. John B. Clark and A. C. Harner, Jr., arrived on this morning's train from the East. Mr. Harner is a son of the President of the newly-organized company in Philadelphia, which purchased from Ben. Fitch the series of copper mines in Kinsley district, in this county. He will act as superintendent, and active operations for the development of the property will be commenced immediately, or as soon as the weather will permit.

Taylor District.

SALES.—Ward Reflex, May 5: Taylor district takes the lead in saleable mining property just now, and justly so. It appears to be no trouble at all to sell a mining claim over there at a good figure.

Tuscarora District.

ELKO CON.—Times-Review, May 6: During the past week drift No. 3 has been advanced six feet through an unusually hard formation; total length, 89 ft. The ledge continues to produce a fine quality of chloride ore.

GRAND PRIZE.—West drift on hanging wall is in 56 ft, and the upraise east of the shaft on the 500 level is up 32 ft.

ARGENTA.—Drift from winze is in 87 ft. Have stopes opened a distance of 40 ft, all in good ore. Repairs on mill are being made as rapidly as the nature of the work permits. Pay roll for April, \$4,029.75.

NAVAJO.—The stopes are producing the usual grade and quantity of ore. Last Monday shipped \$14,233.43, making a total for the month of April of \$83,879.93.

NORTH BELLE ISLE.—South drift has been advanced 34 ft during the past week. East crosscut was advanced 9 ft through exceedingly hard formation, showing small seams of ore.

White Pine District.

HAMILTON NOTES.—White Pine News, May 5: The present weather is a great drawback to mining operations in this section. The Sweetwater Co. is prevented from hauling ore to their mill, owing to the bad condition of the roads.

ARIZONA.

NOTES.—Tombstone Epitaph, May 5: The Lima Con. has determined to let a contract for a further 200 ft in the main shaft, so that with the work being carried forward in the tunnel the work of development goes bravely on.

THE WATERVALE MILL.—Everything at this place is running smoothly, and the stamps are kept constantly running on ore from the Rattlesnake mine, the output of bullion from which shows no diminution. Quite a number of improvements have been made here in the shape of pans and settlers, and there is no doubt but that a further five stamps will shortly be added.

PEDRO CON.—The tunnel is now in 300 ft, in prosecuting which work many seams of ore have been cut through. The main ledge, which is the object in view, will not, it is calculated, be struck for possibly 130 or 150 ft yet.

CHARLES ANSHUTZ. from Bisbee, came in to town to-day. He reports everything booming in the copper camp, with plenty of inquiries for good properties.

THE Silver Bear. at Bisbee, it is said will shortly start up with a full force of men, which will add to the already prosperous condition of this happy camp. Our friend Percy Thompson continues superintendent.

It is with pleasure that we announce the settlement, by a friendly compromise, of the lawsuit of the Satisfaction and Atlanta mining claims at Bisbee. The terms are hard on the innocent purchasers, but, nevertheless, a bad compromise is always better than a costly lawsuit. Work will be at once commenced on the Atlanta, and before long, should the development warrant, the erection of smelters will be carried out, and another bullion producer at Bisbee will soon be heard of.

NOTES.—Arizona Miner, May 4: The Copper Mountain smelter, of Messrs. Stoddard & Co., is up and ready to commence operations as soon as coke for the furnace arrives on the ground, which will be within three or four days. The Copperopolis Co., of Castle creek, better known as the Colyer Co., has a smelter on the ground ready to put up and commence operations. Mr. Klein, President of the company, is at Castle creek looking after the business in person. The Holms mine has at last changed hands, and Mr. H. has received his \$135,000 in cash from Mr. Rodebush for the same. Out in the Black Hills Gov. Tridell and his company are busy preparing for machinery, which is about to be erected for the treatment of copper and silver ores. At Tiptop the new hoisting works are being put up, and soon developments in the mine will commence, and the Gillett mill will start up. On Cape creek, Maricopa county, a great deal of work is being done, and good properties coming to the front. On Turkey creek considerable ore is being taken from the mines and shipped to the Howell smelter on Lynx creek. The Howell smelter has proved a grand success, and a great deal of bullion is being produced which will soon be shipped east. From Mohave county we have flattering reports of big strikes and good sales of mining property.

TODD BASIN.—Mohave County Miner, May 4: The great Wallapai district is divided into a number of sub-districts, each represented by its little mining camp and its particular set of miners. As a rule the inhabitants of these camps are firm believers in their own camps, and will argue by the hour on its distinctive merits, and claim that their mines are the best and that that particular portion of the Wallapai district in which they live is the best and richest. In no case is this spirit more marked than in the sub-district commonly called Todd basin, and in which we will include the neighboring basins, called respectively Bobtail and Union. The miners who own most of the claims in the vicinity of these three basins have a right to brag about them for many reasons, though the simple fact that the rich ores produced here have supported some of them for the past 10 or 12 years, even with the exorbitant milling charges and the corresponding high prices charged for merchandise, should be reason enough.

COLORADO.

IDAHIO SPRINGS NOTES.—Georgetown Courier, May 3: Work is being vigorously proceeded with on the East Hukill lode. Mr. Ward states that his placer is yielding at the rate of \$400 to the man per day. Colonel Sandilge has sold one quarter of his Squirrel Gulch mining property for \$5,000. About 40 men are being employed on the Lone Tree mine and in the Bullion Smelter at Fredland. Work is to be resumed upon the Edgar mine. A contract to run 200 feet on the second level has been let. J. S. Sanderson, Esq., has leased the Cecil mine on Ute creek, to Mr. Stahl, of Denver. Work will be immediately commenced. Mr. Sanderson owner of the Wallace lode, is grading a road from his mine to Fredland, connected with the Spring Gulch road. He has ten men employed. The Robinson and Donaldson Co. are making regular and daily shipments from the Champion mine. The lower levels are producing smeltering ore that mills from \$100 to \$300 per ton. The main shaft is to be sunk an additional 150 feet. It is now 600 feet deep. The Red Elephant company's properties are producing more, and looking better than for several years past. 110 tons of fine ore was mined last month. The Swartz shaft is being sunk an additional 100 feet, which will make its depth 550 feet—the deepest workings on the mountain; 60 odd men are employed in the mine.

IDAHO.

EXTENSIVE COAL DEPOSIT.—Idaho Statesman, May 2: Mr. A. L. Rinearson returned here from his coal interests near Horseshoe bend. He informs us that there have been 480 acres of coal lands located in that vicinity recently, the locators being himself and Messrs. Miner and Stone. Two veins have been discovered, one of three and the other five feet in width. The position of the veins is nearly horizontal. Much excitement prevails, and locations are being rapidly made.

BOOMING.—Judge Heath, of Atlanta, made us a pleasant call Tuesday. The Judge has very valuable mining interests in Atlanta, and will return there as soon as the season is a little further advanced. He says that he and other old timers who have long clung to Atlanta with a faith in the future, built upon a certain knowledge of the rich resources of the camp, are themselves astonished at the recent developments and big results in the mines. The long period of promise and speculation is past, and the time of fruition and realization has come.

MONTANA.

THE ANACONDA SMELTER.—Butte Miner, May 7: It was reported on the street yesterday that the location on Warm Springs creek had been definitely decided upon for the site of the Anaconda smelter, and that operations will be commenced immediately for the erection of works there, but it is questionable whether the location has yet been fully determined upon. It is known that within the past two days surveys have been made for a site on the bench between the Blacktail and Suprenant's arastra, about eight miles southeast of this city. It was stated that, although the facilities for securing limestone, magnetic or hematite iron and fuel at this point were excellent, the difficulty of getting water would prove an insuperable objection to its final selection as the site for the smelter. It is also known that subsequent surveys show that water from the Blacktail could be obtained in abundance, by constructing a three-mile ditch. It is not reasonable to suppose that so eligible a site would be abandoned for one possessing so few advantages as the proposed Warm Springs creek location, unless some special inducements were offered in the way of land grants or special railroad rates, and it is not believed that any such special inducements have as yet been brought to bear upon Messrs. Haggis & Tevis to influence their final selection of a site for the smelter.

NEW MEXICO.

IRON KING.—Southwest Sentinel, May 2: The Iron King and 81 mines are undergoing rapid development. The ore is being hauled to the Magruder smelter under a contract, and each successive ton seems to be improving. Messrs. Magruder, Crawford and Higbee purchased of Messrs. Hutchison, Cassidy and Parker, and others, the ores which will be run through the new smelter at San Jose. An enormous mass of ore is now corded up around the smelter, and more is being added each day. The engine will be fired up in a few days and the smelter running in full blast, with sufficient ore to feed it for a long time to come.

ALMON.—Judge Potter and Mr. Johnson, owners of the Almon mine at Hanover, are now negotiating for the sale of 1,000 tons of ore they have already on the dump. It is copper property, and is considered a mine of great value. The average run of the ore extracted is 15¢. Considering the cheapness with which the mine can be worked, and the excellent facilities for smelting it, both seller and purchaser will make handsome profits. The owners of the Guyanaden copper mine, same district, intend letting a contract this week to sink 30 ft deeper. This property was purchased by Messrs. Reed & McDonald, Chicago mining brokers, when they immediately organized a large company to open it up and put machinery upon the works.

THICKET.—Sam Eckstein, one of the lucky owners of the Thicket mine, is happy. This valuable piece of property is only three miles north of the New Strike. He is down 80 ft on it, and has been rewarded by finding horn silver in large quantities. Specimens of the ore at his place of business are equally as good as anything yet unearthed in the great Bonanza.

MR. BALBACK., superintendent of the Glorieta M. Co., has met with some agreeable surprises in his development work on the Micawber mine at Clifton. From samples assayed under his direction in Silver City the results show a wonderful change in the character of ore. Looking for copper they follow the lead and find a large per cent in gold and silver. The average from a two-foot vein gives \$27.90 in gold; the average from an eight-foot quartz, good and poor, gives \$13.64 in silver; this was from a shaft 52 ft deep, and, as they progressed, when at a depth of 60 ft, the men superintending the contract telegraphed them on Saturday they had struck horn silver. This has given a new impetus to the mines in that locality and will be exceedingly encouraging to the owners. Gold has been found in the vicinity as well as silver, but copper has been so far the most worked and the most looked for. With this new development the Glorieta Co. will show some valuable property.

Peter Cooper.

How strange it is that we never fully recognize the worth of a great, noble nature while among us. It is only after he has gone that we begin to say, one to another, what manner of man is this who walked and communed with us by the way. It is the old illusion of what is present and familiar. The heart fails to realize how precious are its jewels until they are lost. Future generations build the sepulcher of the prophets, and do honor to their name. Peter Cooper works of love and charity fell upon the eager, money-making, giddy people of New York as a gentle rain upon the grass. Now they begin to realize how far-reaching and permanent are his beneficent deeds. Endurance is the only true test of a noble character, and Peter Cooper will be remembered in New York long after her Astors, Vanderbilts, Stewarts, and Goulds are spectral names.

His long, busy, thrifty career is a fine commentary on the law of patient, productive industry. There were hundreds all around him in those early days, as now, who sought to sprout fortunes in hothouse ventures. Mr. Cooper never ran after wildcat speculations. He threw no money into the lottery wheel of chance. He believed that wealth could be had, without making other people poorer. That a dollar judiciously planted would grow a harvest. At seventeen years of age he began the struggle as an apprentice in a carriage shop on \$25 a year and board; and by zeal and diligence won the confidence of his employers. At twenty-one years of age we catch sight of him in a woolen factory on Long Island working at \$1.50 per day. While here he invented a machine for shearing nap from cloth. It was patented, and for a short time had a rapid sale, and put a little money into his pocket. With this he opened a furniture store at Newburg, where his parents lived, which he kept for a short time, and then returned to New York and opened a grocery store. Hearing that an old run-down glue factory was for sale, he purchased it for \$2,000. He was now permanently established in business. It proved the source of the great bulk of Mr. Cooper's fortune. For many years he carried on the business alone, had no book-keeper, no clerk, no agent, no salesman. At break of day he was at the factory starting the fires and preparing for work. At noon he drove down into the city and made his sales. His evenings were spent posting his books, attending to his correspondence, and enjoying the society of his wife. This was his daily routine for nearly thirty years. His money swarmed, and at the age of fifty-five we find him owning rolling mills and iron works at Baltimore, Trenton, New York, Phillipsburg and Williamsburg, giving employment to 2,500 men. Through economy, sagacity and patience, his immense fortune had grown as naturally as the trees grow.

Peter Cooper entered New York with only ten dollars in his pocket. Jay Gould found himself on Broadway with only a patent mouse-trap to begin business. Alone among strangers both resolved to make a fortune. Both succeeded. There is nothing remarkable in all this. New York is full of rich men, who started life as poor as they. The fact is, acquisitiveness is an instinct, and is almost sure to lead to success when the environments are propitious. It is the motive which animated these two men with which we are now concerned. Gould sought for wealth, because it was a scepter of power that awed courts, legislatures, and levied at its own caprice tribute upon the earnings of the people. Here they part company. Mr. Cooper, while an apprentice in a carriage shop and spending his scanty earnings on the teacher of an evening school, determined to devote his years to the accumulation of wealth that he might found an institution where poor working boys and girls might acquire a free education in the prac-

tical arts and sciences. It was forty years before he was able to give definite shape to that idea. But he never forgot it. It gave unity, method, aim, and inspiration to his long years of toil. While carding wool at Hempstead, selling sugar, salt, and fish, at the Bowery grocery, making glue and isinglass at the Old Middle Road Glue Factory, building the first locomotive in America at his Baltimore Iron Works, or manufacturing the first railroad iron in this country at Trenton, during all these busy years, the founding of that school shone like a day-star in his thoughts. At last the time came to realize the beautiful dream of his life. About twenty-five years ago the foundation of the Cooper Union was laid. It was five years before the building was finished. It is a brownstone and iron structure, thoroughly fire-proof, of massive Roman architecture, an irregular quadrangle in shape, having dimensions on its four sides of 90, 146, 165, and 195 feet, and costing \$964,000; exclusive of the institution an addi-

tion has cost \$700,000. Of the splendid success of the institution in supplying the want which it was intended to meet, a recent annual report of the curator gave ample evidence. Every department was full to overflowing. More than 3,000 pupils has entered the various classes. Between 400 and 500 applications has been put on file to await the retirement of those who already held places in the classes. The instruction and lectures which these pupils enjoyed were given to them absolutely without charge. It is not easy to realize the far-reaching and beneficent influence of such an institution. In the twenty years of its operation, it has transferred the lives of thousands of youths from the unproductive and servile employment to which they would have certainly fallen, into the higher plane of intelligent, skilled artisans and original designers in the workshops and schools of the country. It can point throughout the land to miners, engineers, architects, builders, telegraphers, photographers and teachers; even professors in the higher departments of science who have been indebted to it for their success in life. Stephen Girard, ungracious in manner, ill tempered, miserly lived and died without

Stored Energy.

The useful development of electricity is one of the chief marvels of our age. Ever since it slid down from the sky on a kit

PETER COOPER.

string, and learned to respect houses and barns armed with lightning rods, there went abroad an impression that this mighty force could be caught, tamed and harnessed to a great variety of important uses. This expectation has been fully realized. It has been turned into medicine and liver pads, and at a touch of the finger flashes human thought across mountains and under the sea. Within a few years it has been taught to carry the very words, accent and tones of the speaker's voice. It writes for us, rings bells, strikes the time in electric clocks, warns a whole city of the locality of a fire, and floods the streets with a warm, brilliant and beautiful light. But the great trouble has been to manufacture and store it away, as water in a tank, or gas in a reservoir, in short barrel it up and keep it on draught. It is such a sly, subtle, potent energy. But within a year or two past even this marvelous feat has been accomplished. Sir Wm. Thomson's experiment with the Faure accumulator, sent him from Paris to Glasgow, gives perfect assurance that it will not be long till electricity is boxed, barreled and bottled, and shipped all over the world as an article of merchandise.

But in this invention, as in all others, man has only caught a hint from nature. Though to a superficial eye she may seem very prodigal of her energies, the fact is she is very economical and allows no waste. We may feel a little surprised to read that Faure's battery held "a million of foot pounds," yet a pound of coal contains energy equal to eleven million foot pounds. Every drop of water is said to hold lightning enough to kill a man, and in that case a tumblerful is a condensed thunderstorm. The sun pours his beams lavishly upon the earth. Much is radiated, but the earth like a prudent housekeeper, stores the most of it away for future use. It is packed in seeds, garnered in bulbs, blushes in flowers, and comes out in the flavor of fruits. Even cucumbers and radishes are full of sunshine, though it may take a digestive apparatus equal to a quartz-crushing machine to eliminate it. Nature is a careful banker and makes the most of her capital. Nature is generous, because she saves. What tremendous energy is stowed away in gun-cotton, powder, or glycerine. A dynamite bomb that a child could hold in its hand contains a small earthquake. A loaded gun or cannon is a fine sample of stored energy.

Thanks to Mr. Faure for the hint. Now for the application. A newspaper should be a sort of mental battery charged with wholesome ideas, valuable suggestions, a summary of the life and business of the city, a bulletin of the market, an epitome of the State, the nation, the world. It is a portable accumulator that the reader can stuff into his pocket, lay on his desk, or hang on a file until he has leisure enough to put his optic nerve and brain in contact with the magnetic currents of the world.

The sermon the reader listened to last Sunday was the stored energy of a week's elaboration, and if it lacked electric warmth, light and fire, it was because the preacher's brain battery worked badly or he tried to manufacture mental energy out of theological coke or the dust, slag and cinders of medieval theology. It may be that the conditions of the hearer were not good.

A fine physical constitution is a form of stored energy, sometimes inherited, but usually the result of wise and prudent care. For more than three months President Garfield fought death from a mortal wound, for the simple reason that the accumulated power of a sober, chaste and temperate life came to his help.

Good character is another form of stored energy. It is the accumulation of moral force, generated by a long, constant and steadfast resistance of evil temptation in every shape. It is the lack of this silent storage of power, that causes so many to break down the moment any great trust and responsibility are placed upon them. They are like hollow trees that are well shaped and apparently solid and vigorous, but are easily twisted, bent, and broken in a storm.

A CHEAP PAINT FOR FARM BUILDINGS.—Professor Knapp, of Iowa Agricultural College, says that experiments upon the college farm have decided in favor of the following preparation as a very excellent paint for outbuildings, and as far as tested it seems to answer all the conditions of more expensive paints: To three parts crude petroleum and one part linseed oil add sufficient mineral paint to give the desired body and apply with a brush. For better buildings white lead may be added in the proportion of one pound of lead to five of mineral paint. Crude petroleum costs only from six to eight cents per gallon by the barrel, and can be easily obtained through any druggist or dealer in oil in any town or village. A barrel would be handy to have in the house of any farmer, who could then do a world of painting at odd spells. Not only ought barns, fences, hog pens and stables to be painted, but the roofs and floors of these buildings as well.

A Curious Gold Mine.

There is up in Shasta county about ten miles northwest of Shasta city a mine belonging to private parties and now being worked in a small way, which is curious in several respects, there being no other like it, to our knowledge on this coast. It is called the Banghart mine, and has been worked more or less for the past seventeen years. It consists of a combination of claims, separately marked off to different owners. The ledge is in a mountain at the head of the Mad Mule creek, at an altitude of 3,800 feet. It is from 180 to 200 feet wide. The ledge formation is what is called birds-eye porphyry lying between well defined walls of black slate.

In early days Mad Mule Gulch was the richest gulch known in Shasta county. It paid very largely in coarse gold, some very fine large nuggets having been found. When worked out, the parties tried to find the source of the gold, but finally gave up the search no quartz ledges having been found.

Mr. Banghart was in the upper country, and heard of the coarse gold in the gulch. He thought he could find the source of the gold. He went to work diligently, but it was two years before he had any luck. He then discovered that there was a porphyry dike about 200 feet thick lying between slate walls; and this dike was traversed with seams carrying gold, wherever the seams came in contact with the slate walls, but nowhere else. The small seams are composed of magnesian, quartz sulphurets of iron, and they lie in all directions.

In the opinion of those who are working the mine, in the original cooling the porphyry shrank and cracks opened, and the heat from below forced this material up, and deposited it wherever it came in contact with the slate. If they go into the porphyry six inches they do not get any gold. It lies simply where these seams make the contact with the slate. Pieces have been taken out of some of these seams weighing twelve pounds. Last fall a piece weighing three and a half pounds was taken out with only traces of quartz. The gold is not found and taken out every day. They track a seam, and sometimes it will run 100 feet perfectly barren. It opens and closes. At some points it will be six inches in thickness, and contains quite a deposit of gold; then it will not be wider than a sheet of paper, but they keep on following it and it will swell out, and then comes another deposit. The lead has been traced seven miles. Some seams of porphyry are connected with the hanging wall, and pay well. On the hanging wall tons of sulphuret ore are found. The concentrated sulphurets from this run \$1,500 to the ton. The streak is about six inches wide.

This mine has been run by the present owners without any money. It took all they had to buy the mine, but it has paid its own expenses. Sometimes they take out two or three thousand dollars in an hour. It is all drifting work; they run a tunnel in until it strikes the slate, and then run along the slate. They do the same way on each side of the gulch. They dump into the gulch, and have no machinery. They have eighteen short tunnels, fifty feet or so apart. The slate comes to the surface. It is partly stoped out between the tunnels. These tunnels are run where they think they can get the best pay.

Last December, with one man, the streak being worked averaged \$80 a day right along, the largest piece taken out weighed nine ounces. The largest piece of gold ever taken out weighed eleven pounds. Some seams pay well and some very poorly—some only two or three dollars a day, others \$1,000 in an hour.

We were shown this week a box of very handsome specimens of pure gold in what is apparently a crystallized form. The little pocket from which this gold came yielded the other day eighty ounces, including what was shown us. There was no quartz attached to the gold at all. In fact it came out of a bunch of soft manganese, being scooped out with the hands.

The mine is perfectly dry, so no pumps are used, neither is there any timber used nor any hoisting done. The little tunnels which run in as far as the slate walls are run in on the side of the gulch, and the waste is dumped down into the gulch from the mouth of the tunnels. The tunnels are dug fifty feet apart and one somewhat above another. Drifts are run from the tunnels in the search for the seams, and the seams are stoped out.

Mad Mule Gulch yielded, when worked, \$1,000 a foot for three-quarters of a mile, and the gold evidently came from the source we have been describing. The mine is not systematically worked by any means, but is in a manner "coyoted" in the search for pockets. If all opened up properly, with means to do it, a different system would be inaugurated. The ore is pounded out with a spring pole and mortar. Over \$70,000 has been taken from the mine, no machinery having been used. An anastra and a mortar constituted the metallurgical implements. The specimen which took the first premium at the last Paris Exposition came from this mine. The mines of Transylvania, Hungary, as described by Ure, seem to be in a geological formation very similar to that in which this mine occurs.

USEFUL INFORMATION.

Difference Between Dry Rot and Worm Eaten Wood.

Dry rot is a term applied to damp wood under process of destruction by fungi, or low forms of vegetation. The albumen and the essential oils in the wood become the food of this secondary or parasitic vegetation; the woody tissue is broken up, and the walls of the cells destroyed, an earthy, powdery matter being left as the residue. This residue bears on its face a close resemblance to burnt or charred wood. Indeed, it is akin to burnt wood, for the albuminoids and the essential oils which escape under the influence and form the food of fire, have been consumed or absorbed by parasitic vegetation. The residue, an earthy, inflammable substance, is practically identical with that resulting from fire.

Dry rot, or the destruction of wood by secondary forms of vegetation, is dependent upon two conditions—heat and moisture. To prevent dry rot, the wood is dried or seasoned, by which one of the elements is withdrawn. To guard against the return of this one element, the wood is painted or varnished, and hence the general application of paint or varnish. Where wood can not be painted, preservatives are used, the object of which is to change the character of the wood, so far as its secretory matter is concerned. In this direction, creosoting is the most common or customary, the object of which is to poison the albuminoids and the essential oils, and so render them unfit for food to low or secondary forms of vegetable life. Salts, sodas and metallic injections have the same effect, but they are in a large degree soluble in water, and in course of time become weak or disappear, and consequently they are not so largely or generally used as creosote oil. The amount of moisture necessary for the support of this secondary vegetation is very large. This is supplied by humid or stagnant air, or by damp walls or subsoils, and hence it follows that wood subject to passing air, or brought under the influence of vegetation, is free from this disease or dissolution.

Worm eaten wood is wood injured by mechanical action—i. e., by animal life. The same conditions are imperative to the support of this form of life as to the above, but the amount of moisture necessary in this case is very small compared with that required for vegetation. Wood to be worm-eaten must be subject to damp, humid or stagnant air, and it must be a sweet wood, or the sap of a hitter or pungent wood. Ash, elm, walnut, birch, beech and lime-tree are sweet woods, and very subject to worms. Oak and resinous woods are bitter, pungent and unpalatable, and, except in the sap wood, are fairly free or proof against the attack of worms. Under certain conditions, as in the roofs of churches covered down with lead, where condensation of the atmosphere ensues, and the wood absorbs the moisture, the heart wood of even oak will fall a prey to the action of worms. In some cases the necessary moisture is supplied by the ends of the beams being inserted in walls, the materials of which are porous stone. Here the damp ends of the beams will be riddled with worms, and, sponge-like, they will crumble away, and if not supported will fall clear of the walls. The heart wood in this case seems to have lost its pungent qualities and to have become soft with long saturation; but, not having been seized upon by fungi, to still retain its albuminoids, and to be sufficiently endowed with them to form the food of worms.—*Furniture Gazette*.

TO MAKE LUMINOUS PAINT.—The following is a more concise method of making luminous paint than any which we have given before: Take oyster shells and clean them with water, put them into the fire for half an hour; at the end of that time take them out and let them cool. When quite cool pound them fine, and take away any gray parts, as they are of no use. Put the powder in a crucible in alternate layers with flour or sulphur. Put on the lid and cement with sand made into a stiff paste with beer. When dry, put over the fire and bake for an hour. Wait until quite cold before opening the lid. The product ought to be white. Separate all gray parts as they are not luminous. Make a sifter in the following manner: Take a pot, put a piece of very fine muslin very loose across it, tie around with a string, put the powder into the top, and rake about until only the coarse powder remains; open the pot and you will find a very small powder. Mix it into a thin paint with gum water, as two thin applications are better than one thick one. This will give a paint that will remain luminous far into the night, provided it is exposed to the light during the day.

ALANTHUS WOOD.—There have been many suggestions made concerning the use of alanthus wood for furniture purposes, and without having given sufficient thought of its adaptability, it has found many advocates, mostly on account of its attractive appearance when finished. A thorough test was concluded a few days ago, and it was found that the wood was hard to work, and failed to retain its shape. Aside from the desirability of possessing another good furniture wood, this failure is unfortunate in an artistic sense, for the delicate tint and irregularity of the grain would make rich effects.

AMERICANS LEARNING TRADES.—An inquiry set up in Philadelphia for the purpose of ascertaining what proportion of the young men who are learning trades are native Americans, shows rather an interesting result, namely, that in but two of the trades do American apprentices predominate—in the machine shops and printing offices. In nearly all the trades the German apprentices were found to be much in the preponderance. They are learning the trades their fathers learned before them. While they may be fully as successful in gaining a competence, the point is made by one of the Philadelphia papers, and justly enough too, that the American-born boy selects a trade that offers a scope for a higher order of intelligence, if indeed it does not present opportunities for a career. They cannot be accused of selecting trades of the dilettant order, for they are the reverse of that.

IRIDIUM PLATING.—Mr. W. L. Dudley recently announced, before the Ohio Mechanics' Institute, that the problem of electro-plating with iridium has been solved by employing a suitable solution of the metal and properly regulating the electric current. The solution is kept at uniform strength by using a plate of iridium as the anode. The metal is deposited in the reguline state, and takes a good polish. A huffing-wheel that will grind off nickel plating in a few minutes only serves to polish the iridium. Thin platinum foil, coated with iridium, retains its flexibility, and, if the coating is not too thick, it will not readily scale off. Copper plates for engravings, faced with iridium, would possess marked advantages over steel engravings.

SAW MILLS IN THE UNITED STATES.—It appears that there are no fewer than 15,024 saw mills in the United States, and 637 in Quebec, Ontario and Manitoba. The figures of the work performed by these mills are almost bewildering, and during last year nearly 750,000,000 feet more timber was manufactured than in the year 1881. Toward the close of the year new mills were being built in every direction so as to be ready for work this spring; all of which promises to keep insurance companies as busy as ever paying losses on this class of special risks.

FANGS OF THE RATTLESNAKE.—At a meeting of the Philadelphia Academy of Natural Sciences, Dr. Leidy exhibited a series of fangs taken from a rattlesnake fifty-two inches in length. The rapidity with which the functional fangs are reproduced was shown by the presence, on each side of the jaw, of five fangs in varying degrees of development, so placed as to replace those which are lost.

GOOD HEALTH.

Milk in Health and Disease.

Dr. A. P. Grinnell, of Burlington, Vt., recently gave a lecture before the Vermont Dairy-men's Society on "Milk in Health and Disease," a subject that is but just beginning to receive the attention it deserves by the American people. The doctor would have it distinctly understood that the mortality among children, which carries off one fifth of all who are born, before they have completed their first year, and one half before they reach the age of five years, is not as we have sometimes been taught at funerals, the work of Divine Providence, but the result of ignorance, and nothing else. Milk is the natural food of infants and they should have that and nothing else until the teeth are developed, which does not occur until the child is from seven months to a year old. It is not alone the absence of the teeth for chewing, that makes solid food unsuited to an infant stomach.

The food of adult persons is composed largely of starch, and the digestive organs of adult persons secrete fluids which help to digest starchy food, but previous to the seventh month the saliva and the pancreatic fluid have no power whatever to change the starch into sugar and thus render it digestible. Human milk is the best food for children, but since it is becoming unfashionable for human mothers to provide the natural food for their offspring, the milk of other animals may be substituted, and the cow's milk is the best we have, provided it is pure and wholesome. It should not be diluted by adding an equal bulk of water as is too often done. The milk of women and cows is so nearly alike in composition that if the latter be diluted one half by adding water, the child is in danger of starvation. Give the child plenty of pure milk until it is a year old, and nothing else, and it will not die from teething. It is just as natural to grow a tooth as to grow a tail.

The butter, or fat, is a valuable constituent in milk, but milk which has little fat is still wholesome and hearty, because the casein of milk is converted into fat by the digestive organs of the system. Milk as human food is sadly undervalued by the American people. A New York physician, who, at the age of forty years, found his health gone, adopted a diet of boiled milk and rice with nothing else whatever, and lived another forty years in almost perfect health, and was able to do the greatest amount of mental work of his life. Many persons suppose that milk is not adapted to all stomachs, but he did not believe that there is one in a thousand who could not use it with advantage. Milk is now being used largely as a means of restoring sick persons to health. In Pennsyl-

vania, a hospital for the bed ridden patients has become very popular. Patients who have lost the use of their muscles are put upon a diet of milk and nothing else. About two ounces is given at first, once in two hours. In one hour and a half it is digested. The amount is gradually increased till the patient will take a gallon per day. This treatment is accompanied with rubbing of the body, and in a comparatively short time the muscles are renewed, and become healthy and strong enough to allow the patient to get up and walk.

The Aim of Exercise.

It should be understood by the public, as it is known to the profession, that the aim of exercise is not solely to work the organism which is thrown into activity, though that is one, and a very important, part of the object in view, because as the living body works it feels, and as it feels it is replenished; but there is another purpose in exercise, and that is to call into action and stimulate the faculty of recuperation. Those who believe in the existence of a special system, or series, of trophic nerves, will not object to this designation of the recuperative function as a separate "faculty," and those who believe nutrition to be effected in and by the ordinary innervation will recognize the sense in which we employ the term in italics. It is through defect or deficiency in the vigor of this faculty that unaccustomed feats of strength, whether of mind or muscle, are found to be exhausting.

The task is performed, but the underlying faculty of restorative energy, or power of recuperative nutrition, located in the particular part exceptionally exercised, is not in a condition to respond to the unusual call made upon it. When a man goes into training, or, what is practically the same thing, when he habituates himself to the performance of a special class of work, he so develops this recuperative power or function, that the repair or replenishing necessary to restore the integrity and replace the strength of the tissue "used up" in the exercise is instantly performed.

The difference between being accustomed to exercise and able to work "without feeling it," and being barely able to accomplish a special task, and having it "taken out" of one by the exploit, whether mental or physical, is the difference between possessing the power of rapid repair by nutrition, and not having that power in working order—so that some time must elapse before recovery takes place, and during the interval there will be "fatigue" and more or less exhaustion.

The practical value of a recognition of this commonplace fact in physiology will be found in the guidance it affords as to the best and most direct way of developing the power or faculty of recuperation by exercise. Many persons make the mistake of doing too much. Exercise with a view to recuperation should never so much exceed the capacity of the recuperative faculty as to prostrate the nervous energy. The work done ought not to produce any great sense of fatigue. If "exhaustion" be experienced, the exercise has been excessive in amount.

The best plan to pursue is to begin with a very moderate amount of work, continued during a brief period, and to make the length of the interval between the cessation of exercise and the recovery of a feeling of "freshness" the guide as to the increase of exercise. We do not mean that false sense of revival which is sometimes derived from the recourse to stimulants, but genuine recovery after a brief period of rest and the use of plain nutritious food. If this simple rule were carried into practice by those who desire "to grow strong," there would be less disappointment, and a generally better result, than often attends the endeavor to profit by exercise unintelligently employed.—*Lancet*.

DIET IN BRONCHITIS AND ASTHMA.—A full meal with its resulting pressure upon the diaphragm is frequently followed by sudden deaths in patients suffering with bronchitis and asthma. Such persons should always leave the table hungry, and in selecting food should give the preference to concentrated nourishment, avoiding soups or other liquids and all substances the ingestion of which cause flatulence.

BRUISES.—Tincture of arnica is in general use as a lotion for bruises, but its value is greatly overestimated, and it is objectionable in that it sometimes acts as a powerful irritant. The following mixture used as a lotion is quite efficacious and no longer attends its use: Muriate of ammonia, two drachms; vinegar and water, of each two ounces; mix.

STINGS OF INSECTS.—The juice of the red onion is a perfect antidote for the sting of bees, wasps, hornets, etc. If applied freely soon after being stung, it gives almost instant relief. The sting of the honey-bee is always left in the wound and should be extracted before applying the onion juice.

FISSURED NIPPLE.—A simple and safe means for the relief of cracked nipple is to powder it repeatedly with pulverized gum-arabic. Immediately after the child has suckled, the powder should be dusted over the surface, and the nipple protected from the air.

REMOVAL OF STRONG ODORS FROM THE HANDS.—Ground mustard mixed with a little water is an excellent agent for cleansing the hands after handling odorous substances.

Passing Events.

From the mining regions there is little to note, other than we have referred to in our mining summary. Everywhere miners seem to be busy on their claims, working away, prospecting them, or taking out ore. The gradual increase of the mining area of the coast, is bringing many new mines to the front. Moreover it is proving a good thing for old mines also, because new reduction works are going up everywhere, and it has become more common than formerly to work small lots of ore for miners, thus enabling them to get ready money with which to open their mine.

A noticeable feature just now is that the number of assessment mines is becoming much reduced; the levies are less frequent, and for smaller amounts, and new localities are coming into the field. A year ago, twenty-five mines were appealing in May, for \$500,400. This month only sixteen mines can be found in this category, and all they ask for is \$290,400. Of these sixteen mines, ten are in Nevada, and they are asking for \$249,400 of the total, thus leaving only \$41,000 for all the outlying States and Territories on the Pacific coast. There are only three mines in California in the list this month. These are the Campo Seco Copper, and McElroy Gravel, mines of Calaveras county, and the Golden Fleece Gravel mine, of Placer county.

Pool Mining for Gold.

In a recent number of the MINING AND SCIENTIFIC PRESS, we gave a brief description of a method of diving for gold in the streams and rivers of the United States of Colombia. Another interesting method of getting gold, practiced there, is "pool mining." The contrivance of the native for keeping himself at the bottom of a pool while engaged in collecting the detritus and sand from among the holders and out of the crevices in the formation, is very rude but effective. It is as follows: He selects an oblong quadrangular stone, weighing ten or twelve pounds. One side of this he makes concave, to be adapted to the nape of the neck, and then about it he works a netting. To this is attached a broad, flexible band of tough bark by both of its ends, and of such a length as to be slipped readily over the head, from behind, forward as far as the forehead, while the stone is resting on the nape of the neck. With the stone thus arranged upon his neck, and armed with the *almocafre* and *batea*, he is prepared for work.

The *almocafre* is a peculiar tool. The blade has a semi-elliptical shape, is about nine inches long and two inches broad at its base, with a gradual taper to the point, which is blunt. The shaft, which is in direct line with the long axis of the instrument, is cylindrical and receives a handle about eight inches in length. With this implement, which is made of tough well-tempered steel, the gold seeker scrapes and digs among the holders in the streams, and in the cracks and crevices of the strata everywhere.

Being prepared with this, the *batea* and the stone, the miner cautiously wades to that depth where he can retain his foothold, with his head above the water; then, throwing himself forward into the water, the weight of the stone bears his head downward into the pool. At the bottom he secures the *batea* stationary, by putting a stone into it; and then grouping about with the *almocafre* in hand, he scrapes together the auriferous sand and fills the *batea*.

Before the *batea* is loaded, the diver is compelled, perhaps several times, to rise to the surface for fresh air, and this he does by slipping the band from his forehead and casting off the stone. After rising to the surface he swims to the place where he can gain a foothold as before, and then drawing towards him the stone, by means of a cord attached to it, he replaces it upon his neck, and after he is sufficiently refreshed dives in the same manner again. The *batea* is necessarily always retained where the depth of the water is not greater than the diver's height, as it would be otherwise impossible for him to raise the *batea* full of sand. By this rude and tedious management does the gold washer obtain gold from the bottom of pools, which have not, generally, a greater depth than his own height. In this country this kind of gold mining has been done by dredges and vacuum pumps; but our system has the disadvantage of not getting any gold though more sand and water is raised. At least that has been the experience so far.

Local Manufactures.

Probably one of the most prosperous signs of the times in California is the apparent, gradual growth of local manufactures. In this city our manufacturing interests are slowly, but surely being enlarged in scope and variety, and most of them are in a prosperous condition. In Oakland the establishment of manufacturing industries is advancing in a marked degree. Along the water front and line of railroad, the building of several growing industries may be seen. Other towns are following the examples thus set, and manufacturing establishments, on a small scale it is true, are coming to the front. Our home products are varied and abundant, and since our attention has been turned to them more closely, we have, as a community, become more prosperous.

Now that the natural products are increasing we must continue to increase our manufactures. Our raw material should more of it be worked up at home; and, as this plan is more fully carried out, the cities and towns of California will be richer and the inhabitants more prosperous. We see the gradual growth of these manufacturing establishments with pleasure, because they promise a brilliant future for California. With these we are more independent, and our youth find employment at home. Every establishment of the nature alluded to does its share in the good work, and should, therefore, be encouraged by all good citizens.

Hoisting Ropes and Drums.

The diameter of a winding drum is determined mainly by the nature of the rope to be used, a much larger diameter being required for wire ropes than hempen ropes. But it should also bear some proportion to the diameter of the rope of a given material, since it is obvious that the thicker the rope the less readily it will coil upon a cylinder of a given diameter. A suitable diameter of the drum may be obtained in the following manner: Assuming ten feet to be the minimum diameter for a wire rope one inch in circumference, add six inches to the diameter of the drum for every increase of a quarter of an inch in the circumference of the rope. Thus a rope two and one half inches in circumference will require a drum $10 + 4.5 = 14$ feet 6 inches in diameter, and a rope of three and one half inches will require a drum of $10 + 7.5 = 17$ feet, 6 inches. As the diameter of the pulley and of the drum is increased, the life of the rope is lengthened, and it is obvious that, determined by the conditions of the wear in the rope, the diameters of the pulley and of the drum should be equal.

Round rope is wound upon the drum in parallel coils, and in some instances it is made to rise and return upon itself on cylindrical drums for the purpose of diminishing the length of the latter; the arrangement is, however, unfavorable to the durability of the rope. When the drums are conical, the overlap, is, of course, impossible, and the same necessity for it does not exist. A flat rope is always wound upon itself, so that its coils are all in the same vertical plane. Hence, practically, the diameter of the drum is constantly increasing or decreasing, and the velocity of the load consequently accelerated or retarded. This variation tends, of itself, to render the work of the engine unequal during the raising of the load. But it will be observed that this tendency is counteracted by a variation in the value of the load during the same time, and that, consequently, this overlap of the rope results in an equalization of the work of the engine. When the load starts from the bottom of the shaft it has its maximum value, for at that moment the weight of the whole length of the rope is added to that of the cage with its contained load; and it has been shown that the resistance due to the inertia of the mast must also be overcome at the moment of starting. But when the load has thus its maximum value, the diameter of the drum is at its minimum value, since the rope is then wholly uncoiled, and hence the leverage in favor of the load will also have reached its lowest limit.

Moreover, as the other portion of the rope will, at the same moment, be wholly coiled upon the drum, the latter will, relatively to this portion, have attained its greatest diameter, and, consequently, the leverage in favor of the descending load, consisting of the empty cage, its highest value. These circumstances are evidently favorable to the equalization of the work of the engine, and it will be seen that these circumstances continue throughout the time of winding. For, as the one portion of the rope ascends and diminishes in weight, the leverage in favor of it increases in a like degree, and as the other portion descends and increases in weight, the leverage in favor of it is diminished in like manner. The same advantages are obtained with round ropes, though under less favorable conditions, by making the drum conical. When the drum has this form, there is a liability of the rope slipping if any hitch should occur to slacken it, and such a slipping would probably cause rupture of the rope. The length, or as it is sometimes described, the breadth of the drum is obviously least with the flat rope.

When both portions of a round rope are wound upon the same drum, the length of the latter will be that required by a single rope, since one portion is being unwound while the other is being coiled upon the drum, so that the sums of the lengths coiled at any given moment is equal to the length of one portion of the rope. In such a case, one portion of the rope is wound over the drum, and the other portion under the drum. As both portions are wound over the pulley, one is thus wound in contrary directions, a circumstance unfavorable to its durability. The evil is removed by the use of two drums revolving in contrary directions, an arrangement which allows both portions of the rope to be passed over the drum.

The details of fixing the rope to the drum are very simple. Usually a notch or a groove is provided on the drum to receive the end of the rope, which is held by wedging. To avoid bringing the strain of the load upon this fastened end of the rope, the length is always regulated to leave two or three coils upon the drum when the cage is at the bottom of the shaft.

Patent Office Work.

We see it stated that pursuant to a clause in the Legislative, Executive and Judicial Appropriation bill, there will be a reduction in the clerical force of the United States Patent Office, on or before the first of July. Assistant Secretary Joslyn says, that from the overcrowded condition of the business of the Bureau it would not justify this reduction, the force now being smaller than it should be under this clause. There will be twenty-one dismissals.

It may not be generally known, but the fact is the Patent Office is a department of the Government which is not only self-supporting but profitable. The inventors of the country pay for the service which is rendered to them, and pay for it well; and they help others out by giving more money than is used for their good. The surplus earnings of the Patent Office are absorbed by the Government and used for other things.

It seems absurd, under these circumstances, to cut down the force in the office on the plea of economy, to a point where the interests of inventors suffer. The force is small enough now, so that the business does not go on quite as promptly as it might, were plenty of help employed. To still further reduce the force will be injurious.

The Patent Office does not keep what it saves, but turns it over to the U. S. Treasury, and then has to depend on appropriations for its support. With small appropriations the service is crippled and inventors lose time. It would seem but just that when the department earns plenty of money, it ought at least have enough of what it earns to be carried on properly. It is unjust to a very large and valuable class of the community, that their business should be interfered with by such a system as now prevails. There are many hundred thousand dollars to the credit of the Patent Office, and its efficiency should surely not be crippled by withholding this, and giving a scant appropriation. Some day the system will be changed.

Nevada Bullion.

The *Enterprise* says that, according to the generally accepted figures, the product of the Comstock lode may be thus in chief part distributed:

Belcher, 1871-'76.....	\$ 33,053,000
Caledonia.....	212,761
Crown Point, Nos. 1 and 2, 1871-'76...	29,780,000
California, 1876-'81.....	46,850,000
Chollar, 1866-'77.....	13,860,450
Confidence.....	915,000
Consolidated Imperial.....	240,839
Consolidated Virginia, 1873-'80.....	64,970,000
Gould & Curry, 1860-'71.....	15,644,200
Gold Hill.....	26,310,000
Hale & Norcross.....	8,010,800
Justice.....	3,270,000
Kentuck, 1865-'76.....	4,500,000
Ophir.....	11,800,000
Overman.....	1,581,000
Savage, 1863-'73.....	15,800,000
Sierra Nevada.....	1,300,000
Silver Hill.....	138,000
Succor Mill.....	60,000
Trojan.....	71,200
Yellow Jacket.....	14,647,400

Total.....\$293,018,150

Nevada has contributed about \$476,000,000 to the world's stock of the precious metals, of which at least \$140,000,000 was in gold, the chief part extracted from the argentiferous ores. Of this vast sum a single lode supplied from \$293,000,000 to \$315,000,000. A mean between the various estimates would make the product about \$306,000,000.

THE OVERLAND MONTHLY.—The *Overland Monthly* for May is an excellent number. It is thoroughly readable from beginning to end, with a pleasing variety of style and theme. "Pacific Home Making," is a sketch delightfully true to our California conditions, and contains many useful suggestions. Gen. Kautz's "Notes of Travel in Mexico," is another local subject. There are others just as acceptable which we have not room to specify. The editorial departments of the magazine are well done. The *Overland Monthly* is now published by Samuel Carson, 120 Sutter street, S. F.

VILLARD telegraphs that through connection to the Pacific coast is insured by August,

The Bleiberg or Carinthian Process.

A method of lead smelting, known by the name of either Bleiberg or Carinthian process, is pursued in the neighborhood of Bleiberg, in the province of Carinthia, in Austria, where it is employed for the smelting of a comparatively pure, but practically nonargentiferous galena. The process involves three stages. 1. Roasting or calcination of the ore at a gradually increasing temperature, for the production of plumbic oxide and sulphate. 2. The liberation of metallic lead, due to an increase in the temperature of the furnace, accompanied by vigorous rabbling, whereby the unaltered plumbic sulphide reacts upon the oxidized products of lead in the manner already described. 3. Reduction by carbonaceous matters of the oxidized compounds of lead, present in the slag produced in the last stage.

When pure ores, that is, such as do not contain much silica, although small quantities of lime, baric sulphate (heavy spar), and zinc blende may be present, are operated upon by this method, it affords a purer and softer lead than most other methods, with a good yield of metal, and with the production of only a small quantity of slag, which is, moreover, poor in lead; but for these results the process entails a large consumption of fuel, with a considerable expenditure of time and labor.

The Bleiberg reverberatory furnace, as shown in the engraving, consists of a chamber, *a*, measuring about 10 feet, 3 inches, from back to front, and about 4 feet in width at the back; while from the middle to the front or working door, *b*, it gradually narrows as shown. The fireplace, *d*, is a long, narrow chamber along one side of the furnace, the back of which, however, only receives the fuel, and communicates with the atmosphere from beneath: so that the flame passes over the fire bridge, *m*, along the surface of the bed or hearth of the furnace, and escapes by a flue situated immediately over the working door to a chimney, *c*, about 27 feet in height, and which serves for a pair of furnaces, usually built together. The bed of the furnace is formed by first ramming upon the brickwork a layer of clay, of about 6 inches in thickness and shaped to the form of the bed, while upon this rests the working bottom, formed of lead slabs of about the same thickness. The finished hearth is hollow or concave from side to side, and slopes gradually from back to front, or from the fire-bridge to the flue as shown, so that the melted materials from all parts of the furnace drain down to the lowest point at the front end of the bed, where the tap-hole is placed, and from which the metal flows from the furnace into a trough, *n*, placed outside. In front of the working door is a flue, *p*, which communicates with the main flue leading to the stack, and which serves to carry off to the latter any deleterious fumes escaping from the working door. The fuel employed in this furnace is generally spruce and pine woods; but by a little alteration in construction it permits of the substitution of brown coal in lieu of the wood.

The charge of from three to four cwt. of ore is introduced on to the hearth through the door, *b*, at the front of the furnace, and is spread uniformly over the surface of the hearth, where it is exposed to calcination at a low temperature, during from three to three and a half hours; and during this stage the mass is frequently rabbled, while at its conclusion the temperature is raised, and the charge again rabbled vigorously, when mutual decomposition of the plumbic oxide and sulphate with plumbic sulphide ensues, constituting the second stage of the operation, during which the separated lead runs from the tap-hole into the cast iron pot placed outside for its reception; and when lead ceases to flow, the residue or slag remaining upon the hearth of the furnace is either thickened by the addition of the ashes and small charcoal from the ash-pit, and then drawn from the furnace until another charge has been worked off, when the slag from the two charges is treated together, or, instead of this withdrawing the first charge, while a second is worked off, the slag may be at once treated with charcoal, constituting the third stage of the process, in which case the mixture of slag and small charcoal is thoroughly rabbled, and the temperature raised considerably with the maintenance of a reducing atmosphere in the furnace, whereby the plumbic oxide and sulphate of the slag suffer reduction by the carbonaceous matters, yielding thereby about 20 per cent. of metallic lead. The whole operation of working off two charges of ore in this manner, with the separation of metal from the slag produced by the first operation, occupies from 21 to 23 hours,

New Cabinet Steam Bath.

The engraving on this page illustrates a new device, by means of which, either a steam or hot air bath may be taken in one's bedroom. It is called a cabinet steam bath. It consists of a simple cabinet, arranged so as to be readily moved, and having a peculiar door, *B*, hinged so that a portion of the top opens with it. A section of the top on each side has a small circular cut, *c*, in it, and one half of this, *b*, is hinged to the main door, *B*, as shown; two small handles being provided by which the section, *b*, may be moved up or down, as required by the occupant, and without an attendant. At one end of the cabinet, *a*, is a small cupboard-like space in which is placed a pair of alcohol

GALLAND'S PORTABLE STEAM AND AIR BATH.

lamps. Over these is placed a perforated iron grating, so that the flame of the lamps cannot rise too high, and is kept confined under the grating. This grating is arranged also to receive a shallow pan, into which water is placed so that steam may be produced. The bather enters the cabinet, closes the door, places his neck in the cut, *c*, and then closes down the other lid, *b*, so that nothing but his head is outside of the cabinet. The heated air soon fills the cabinet, or in case water has been placed in the pan, steam will fill the space so that either hot air or steam baths may be taken. The bath is prepared instantly, while one is undressing, and there is no danger of inhaling hot air or steam. The device is very portable in its nature, and can be moved readily about a room. It gives one

enhanced if the cars were run by a steam locomotive which could round the short curves of that road, Mr. Cooper built one which he called the "Tom Thumb." It had an upright boiler twenty inches in diameter by five feet high, fitted with gun barrels for flues. It had a single cylinder three and one fourth inches by fourteen and one fourth inches. The engine drove a large gear which meshed into another smaller gear on the axle. The fire was urged by a fan driven by a belt. The driving-wheels were two and a half feet in diameter. The wheels were "coued," and this was the first use of this principle as applied to car wheels, and was suggested by Mr. Knight, chief engineer of the road. On the 28th of August, 1830, the first railroad car in America, propelled by a locomotive, was tested on the Baltimore & Ohio road. The

"Tom Thumb" was coupled to a car in front of it, containing a load of four and a half tons, including twenty-four passengers. The trip of thirteen miles was made in one and a quarter hours, the best time for a single mile being three and one fourth minutes. The return trip was made in fifty-seven minutes. [On another page of this issue reference is made to the more prominent events in the life of the late Peter Cooper.—EDS. PRESS.]

PROGRESS OF THE BIG BEND TUNNEL.—The following progress was made in the tunnel of the Big Bend Tunnel and Mining Company, Butte county, Cal., for the month of April, 1883: Total number of holes drilled, 866; total depth of holes drilled, 5,412 feet; average depth of

Longitudinal Vertical Section of the Bleiberg Furnace.

Plan of the Bed of the Belding Furnace.

an opportunity to take a Turkish bath in his own room. Various styles of this cabinet bath are constructed, the price being graduated according to finish. The lamps may be adjusted from the outside by an attendant or from the inside by the bather. The bather sits, while taking the bath, upon a stool with a perforated leather seat, and so arranged as to be adjusted according to the height of the person using the bath. B. Galland, 303 Montgomery street, the inventor, has several styles on exhibition at his place of business. The bather does not sit immediately over the lamps, but to one side of them, though the heat is disseminated throughout the confined space in the cabinet.

The First American Locomotive.

We copy from the American Car Builder the accompanying cut of the first locomotive

Peter Cooper's Engine.

constructed in America. It was built in 1829 by Peter Cooper, who at that time owned lands on the Baltimore and Ohio Railroad, which had been constructed to be operated by horses. Believing that the value of the lands would be

holes drilled, 6.24 feet; number of pounds No. 1 powder used, 2,450; number of pounds No. 2 powder used, 1,000; number of drills sharpened, 710; time occupied in drilling 121 hours, 01 minutes; average time per shift, 1 hour, 20 minutes; number of carloads of rock extracted, 3,911; tunnel advanced per month, 345 feet; previously reported, 1,397 feet; total tunnel built to May 1, 1883, 1,742 feet. Owing to nine days' trial of a new rock platform in the tunnel, work was very much delayed. Had they been running as usual and no new things to experiment with, they should have made fully 400 feet progress instead of the 345 feet reported. The size of the tunnel is 10x16 feet, and the drills used are Ingersoll's.

CARRYING GOLD DUST.—In talking with the messenger this afternoon, a reporter was told of some of the peculiar plans that have been adopted for carrying dust from the mines into town. He said, to avoid suspicion, the dust is sometimes wrapped up in an old grain-bag and thrown into a water-bucket, hung beneath a mountaineer's wagon; or it is carelessly thrown into the bottom of the wagon in some straw where a robber would not think of looking. But this method is seldom adopted these days. The dust is consigned to the protection of the express agents who lock it up in their box and send it off under the guard of heavily-armed messengers.—Butte Record.

FOLLOWING is a statement of the April million product of the annexed mines:

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening, President Davidson in the chair. The following resident members were elected: William McM. Woodworth, Edward L. G. Steele, Walter M. Wolfe, Rev. E. L. Green, August Lillencrass, M. D., Judge Samuel J. Clarke, J. A. Richardson, and there was proposed for membership Chancellor Hartson. Among donations to the museum: L. Belding, of Stockton presented fifteen land and freshwater shells and ten rare sub-tropical varieties of birds from lower California, of which two are new. W. G. W. Harford presented a large green turtle finely mounted and six species of fish. Capt. F. T. Gilmore, seventeen specimens minerals from Oregon, including copper, iron ore (39 1/2 per cent.) manganese, hematite, chromite iron and coal. H. H. Bigelow, a large specimen of silicified wood. George Davidson, two rocks from Cerro Rohles, New Mexico. Jacob Z. Davis, a botanical album of Colorado wild flowers. Prof. John G. Leunmon, a valuable collection of seventy-one of the most interesting plants of Arizona, including seven large, showy new species. Seth Cook donated twenty-five volumes, including reports of the United States fish commission, etc. L. Belding also presented four photographs of Lower California natives, including the tribe of Yaqui Indians. Professor Davidson transmitted from the transit of Venus commission, thirteen photographs of the transit of Venus, December 5th and 6th, 1882, taken at Cerro Roblero station, New Mexico. The Superintendent of the United States Coast and Geodetic Survey sent a photographer to the National Observatory and had these prints made for this Academy.

A report was read from the committee appointed to prepare resolutions concerning the deposition of Robert E. C. Stearns, of Berkeley, Ph. D., who is about to leave California to be attached to the Conchological Department of the Smithsonian Institute at Washington. The report was as follows:

WHEREAS, It has come to the knowledge of this Academy that R. E. C. Stearns, Ph. D., who for many years has been associated with this body as Trustee, as well as one of its most active workers in science, is now about to leave our State, and as it seems to us that our brother should by no means quit us without some token of our appreciation of his great service, not only to us as a body, we therefore ask to have placed upon the records of this Academy our appreciation of the worth, ability and enthusiasm of our fellow member, and our deep regret that he not only leaves our body but is compelled to quit the Western Coast. Dr. Stearns has been identified with the earlier struggles of the Academy. He has brought to its councils an abiding faith in its success; he has enriched its proceedings with the thoroughness and honesty of his work, and he has exhibited the greatest breadth of view in his deductions and scientific investigations. We shall lose him, but not wholly, for his heart will be with us, and his pen and pencil will yet add their value to our work. We wish him God-speed in his new field of labor, where he is already so well known and appreciated. The Smithsonian can have no better man and no more able and conscientious a worker.

The above report was ordered spread on the minutes.

A. Wendell Jackson Jr., of the University of California, read a paper on the "Structure and Genesis of the Bassick Ore Deposit of Custer county, Colorado."

News in Brief.

Not less than 18 or 20 different persons in eastern Butte are beginning to raise carp.

A LAW has been made in New Jersey to prohibit the sale of tobacco to minors. A fine of \$20 is imposed upon the sellers who disregard it.

At Boston, Saturday, 7,000 people witnessed the close of the horse vs. bicycle race. The score stood: Horses, 911 miles; bicycles, 899 miles.

The Polar exploring ship Willem Barents, has sailed from Amsterdam for the arctic regions in search of the Dutch Arctic expedition in the Varna.

The widow of Prof. Henry Draper has given \$6,000 to the National Academy of Science, to be used in conferring medals for discoveries in sciences.

The largest vessels in the English Navy cost a million and a quarter dollars to build, and nearly a thousand dollars a day to keep them at sea afterward.

The Williams & Guion line steamship Alaska, has made the trip from Queenstown to New York in six days, twenty-three hours, forty-eight minutes.

AN Enterprising youngster of Los Angeles retails tarantulas by the canful, on the streets. The price is 25 cents per tarantula, and lots of custom at that.

OFFICIAL reports from the Governments of Fama, Simbeersk and Astrakhan, Russia, state that the crops are a total failure and famine is expected.

THE Nez Perce Indians, to the number of 125 adult males, held a council the other day, and decided that they were opposed to the building of a railroad through their reserve.

PROFESSORS Blake and Rolker have come from the East to Arizona to testify as experts in the coming trial of the Copper Queen Company vs. the Copper Prince Company.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

ANTI-SCALE COMPOUND

Manufactured by RICKARD & DURDEN.

We guarantee that, with proper use, the Compound will remove and prevent all INCRUSTATION IN STEAM BOILERS.

Ten years trial, in widely separated localities, has demonstrated the value of this invention, and its applicability to different qualities of water. References cheerfully furnished to any one wishing same.

TEN POUND SAMPLE BOX FURNISHED FREE ON APPLICATION.

BERRY & PLACE MACHINE CO., Sole Agents,

No. 8 CALIFORNIA STREET, S. F.

READY FOR DELIVERY.

LATHES, DRILLING MACHINES, PLANING MACHINES

And Other Machine Tools.

STRONG, DURABLE AND SUPERIOR TO IMPORTED MACHINES.

Wheel Cutting to Order.

SAN FRANCISCO TOOL CO., - - 21 Stevenson St., S. F.

Mining Engineers.

LUTHER WAGONER, C. E., M. E.

JOHN HAYS HAMMOND, M. E.

Wagoner & Hammond, MINING ENGINEERS,

318 Pine St., San Francisco, and
Alamos, Sonora, Mexico.

Special attention to the designing and construction of Concentration Works for all ores. Gradual reduction by rolling impact, classification by air currents, improved pointed boxes and corrugated rubber and iron Rittinger tables.

Correspondence and samples solicited from parties having low-grade properties.

MINES REPORTED UPON.

GEORGE MADEIRA,

Geologist and Mining Engineer.

Reports on mines furnished; Estimates of Machinery etc. Special attention paid to the examination of mines in Mexico, California, Arizona and New Mexico. Thirty years in the mines of the above States.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER.

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT OUT and SLOT PUNCH SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

CHICAGO

FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS
For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,
Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. **SPECIAL FURNACES FOR COPPER SMELTING.** Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES
Wire Rope, Safety Cages and any Size and Forms of Cars. **McCaskell's Patent Car Wheels and Axles—Best in Use.**
Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

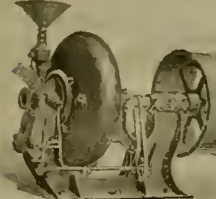

Frue Ore Concentrator, or Vanner Mills.
Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trummels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.
HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,
Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.
CORLISS ENGINES from 12x86 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x30. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivers Hand Driven.

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. R. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Holts for Prospecting, 4 H. P. to 6 H. P.**
New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL.

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Simeco-Martin steel, and all parts mechanical in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lb. It will pulverize 7 to 10 Tons in 10 Hours with 20 H. P. For circulars and full particulars apply to or address,

THOS. F. ROWLAND, Sole Man'fr, Brooklyn, N. Y.

The Crowning Culmination! A \$5 Book for \$2.50!!
MOORE'S UNIVERSAL ASSISTANT,
And Complete Mechanic.
Revised Edition, contains over 1,300,000 Industrial Facts, Canals, Rivers, Harbors, Trade Routes, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer, and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Foundries, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Brongers, Gliders, Metal and Wood Workers of every kind, Builders, Manuf'rs and Mechanics. 500 EXPLANATIONS of Mill, Steam, and Mining Machinery, Tools, Sheet Metal Work, Mechanical Movements, Plans of Mills, Boats, Bridges, etc. Arrangement and Speed of Wheels, Pulleys, Drums, Belts, Saws, Boring, Turning, Planing, & Drilling Tools, Hammers, Saws, Shingles, Paper, Cotton, Woollen & Filling Mill Machinery, Sugar, Oil, Marble, Three-hung & Rolling Mill, do. Cotton Gins, Presses, &c. Strength of Teeth, Shiftings, Belting, Friction, Lathes, Gearing, Screw Cutting, Finishing, Engine Building, Repairing and Operating, Setting of Valves, Eccentrics, Link & Valve Motion, Steam Packing, Pipe & Boiler Covering, Seal Preventions, Steam Heating, Ventilation, Gas & Water Works, Hydraulics, Mill Dams, Horse Power of Streams, etc. On Blast Furnaces, Iron & Steel Manufacture, Prospecting and Exploring for Minerals, Quartz and Placer Mining, Assaying, Amalgamation, etc. 104 TABLES with 300 calculations in all possible forms for Mechanics, Merchants and Farmers. 850 Items for Printers, Publishers and Writers for the Press. 1,000 Items for Grocers, Confectioners, Physicians, etc. 220 Health Items. 200 do. for Painters, Carpenters, Glaziers, etc. 500 do. for Watchmakers & Jewelers. 400 do. for Hunters, Trappers, Tanners, Leather & Rubber Work, Navigation, Photography, Book-binding, etc. In detail, Strength of Materials, Effects of Heat, Fuel Values, Specific Gravities, Weights by rail and water—a Car Load, Stowage in Ships, Lower of Steam, Water, Wind, Shrinkage of Castings, etc. 10,000 Items for Housekeepers, Farmers, Gardeners, Stock Owners, Beekeepers, Lumbermen, etc. Fertilizers, full details, Rural Economy, Food Values, Care of Stock, Remedies for do., to increase Crops, Root Diseases, Training Horses, Steam Power on Farms. **LIGHTNING CALCULATOR** for Cubic Measures, Ready Reckoner, Produce, Rent, Board, Wages, Interest, Coal & Tonnage Tables, Land, Grain, Hay & Cattle Measurement, Seed, Ploughing, Planting & Breeding Tables, Contents of Granaries, Cists, Tanks, Cisterns, Boilers, Logs, Boards, Scenting, etc., at sight. Business Forms, all kinds, Special Laws of 19 States, Territories and Provinces (in the U. S. and Canada), relating to the Coll. of Debts, Exemptions from Forest Sale, Mechanics' Lien, the Jurisdiction of Courts, Sale of Real Estate, Rights of Married Women, Interest and Usury Laws, Limitation of Actions, etc.
"Forms complete treatises on the different subjects."—*Sci. Am.*
The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Free by mail, in fine cloth, for \$2.50; in leather, for \$3.50. Address National Book Co., 73 Beekman St., New York.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

WINDOW SASH.—Alexander Rudolph, S. F. No. 276,887. Dated May 1, 1883. The invention relates to certain improvements in window sashes of that class in which the frame holding the glass is pivoted on supplemental side bars, which slide up and down in the window casing; and it consists of a window sash and supplemental side bars, having corresponding longitudinal grooves and tongues to make a tight joint between them when closed together, in combination with central pivots and supporting center pieces having double inclined sides. These pieces slide obliquely through slots in metallic plates which are fixed to the side bars, so that the bars and sash may be separated when the sash is to be turned, and kept apart and brought into contact again by gravitation alone. When the lever is turned to release the parts they are closed together again by the weight of the sash. In connection with these devices are certain novel features of construction.

WINDOW SASH.—Alexander Rudolph, S. F. No. 276,886. Dated May 1, 1883. This improvement in window sashes consists of a sash pivoted at each side to a guide piece, these guides fitting into grooves in the frame, so as to run up and down, and the pivots allowing the sash to be turned, and in combination with these a series of hooks or clasps, by which the sash and guide-pieces are drawn closely together to exclude air, and are supported by the heel of the elasp when unlocked. It also consists of a peculiar heveled projecting plate upon one side, and a corresponding socket upon the other, where the pivot pins unite the sashes to the guide pieces, which serve to force the sashes away from the guide-pieces when they are turned, and thus concentrate all friction to a point about the pivot pins.

POSTAL SCALES.—J. Frank Miller, Oakland. No. 276,601. Dated May 1, 1883. This invention relates to an index or self-registering balance scale, which is specially intended for postal or other similar purposes; and it consists of a series of graduated weights suitably supported so as to be lifted consecutively and in a manner to counteract oscillation by means of a lever arm, which has the weight supporting pan upon its outer end, so that when it is raised it will lift the weights successively from their support as it moves. A curved, graduated scale is fixed so that an index pointer upon the end of the lever will indicate the weight, or its equivalent postage, the moment the letter or other object is placed upon the pan; or the pointer may be fixed and the graduated arc made movable.

POST DRIVER.—Harry E. Fairman, S. F. No. 276,677. Dated May 1, 1883. The invention consists in planting the ends of the weight guides or leads firmly on the ground, by rocking the axle with which the machine is connected, in a means for adjusting the perpendicularity of the weight guide, and in a novel device for holding the post steady, and in a novel raising and tripping mechanism for operating the weight. The object of the invention is to furnish a machine for driving posts for fences, etc., which may be readily taken from place to place and be firmly stationed to complete the work of driving the post.

CASPAR COURIER.—This is the name of a new weekly at Caspar, Mendocino county, by Chas. B. Huse. Mr. Huse is a young man of spirit and industry, and will, we expect, do much to make better known the resources of his part of a rich country. He has our best wishes.

ENRICH and revitalize the blood by using Brown's Iron Bitters.

Notes from Eureka, Nevada.

[From Our Regular Correspondent.]

There is little or no change to note as, having taken place, since my last letter to the MINING AND SCIENTIFIC PRESS, on Ruby Hill. The Locan shaft has been sunk about thirty feet, and is now down 1,110 feet from the surface. At the furnaces there are signs of increasing production in the small mines. The Eureka Con. floors are full, the Richmond hins contain more ore than I have seen in them for many months past, and the floors are crowded. At present the continued stormy weather has left the roads in a heavy condition, but when they become dry and firm, it is expected that the shipments of custom ores will increase rapidly. The ore body in the Home Ticket mine is increasing in size, and about sixty tons per week are being sent to the furnaces. This mine is one of the Ruby-Dunderberg series. The company is sinking a new shaft, and building new ore platforms about forty feet from the side line of the Golden Rule series, and the last named property is consequently becoming more valuable. The Golden Rule Con. Co. are driving their tunnel ahead, and will soon tap the ore body, presumably the same that is being developed in the Home Ticket mine, as that is striking toward the Clipper location of the Golden Rule series. On Wednesday last, a vein of quartz six inches thick was cut in the Golden Rule crosscut, which is being steadily pushed ahead with increase of good prospects.

The Eureka Tunnel.

Which is within a thousand feet of it, is looking well, as usual, and better if anything. The Engine shaft is down to the 105 level, and connection has been made with the No. 3 drift. There is a small but rich streak of galena near the point of connection in the drift, and above it is a seam of good carbonate, ledge matter a foot thick between the hoth. The No. 2 winze has been connected with the bottom of the Addison chambers—south end. Here the ore body is about twelve feet high, sixteen feet wide, and twenty feet long. Four feet in thickness of this is very high grade ore, and the balance is of good quality. A raise is being made in the Addison chamber, north, in a northeasterly direction, on ore now up 20 feet. At

The Alexandria Mine

The Dilligent shaft is down 200 feet and cribbed 100 feet. Here a station will be cut out. The next station below this point will be at the 200 foot level, and another will be cut out at the 315 foot point in the shaft, from which a drift will be driven northerly to connect with the old Alexandria incline. In the Sterling tunnel, which is a part of the Alexandria workings, about five tons of high grade ore is lying awaiting shipment to the smelters.

At the Frankie Scott Con. the lessees are driving a tunnel from the Charlotte location to connect with the old works, for the purpose of facilitating the removal of waste rock, and extracting ore. They will commence shipping ore in a week or ten days.

Ore Shipments

Will be resumed from the Great Republic in a few days. The ore from this mine is of good quality, and there is a great quantity of it upon the dump.

The Ruby Hill tunnel on the west side of Prospect mountain, is in 210 feet from the crosscut with a seam of ledge iron in the face. The Richmond Con. Co. is prospecting steadily in the Hoosac mine, on Hoosac mountain, and the lessees of the Rocky Point mine, which is situated on the north end of the same mountain, have just shipped seven tons of heavy galena ore to the Eureka Con. furnaces. Ore is being extracted from the Williamsburg mine, north of Adam's hill, from a vein about one foot thick. It is of fair grade, and carries a high percentage of lead. At the Altoona mine, on Adam's hill, the main shaft is down eighty-five feet, and a crosscut is being driven through ledge matter, and low grade ore, which it has penetrated ten feet. The appearance is very promising, and sufficient to justify the hope of discovering a larger body of ore than any yet found in Adam's hill. On the May ledge, a new shaft has been started in the cap rock, and some ore of excellent quality is being found in the crevices; an assay from thick, gave \$55 in gold, \$67 silver, and 20% lead. A few feet easterly from the Altoona shaft is a hole ten feet deep, out of which was taken fifty tons of ore which worked at the furnaces \$108 per ton, and five tons that yielded \$290 per ton. Considerable work is being done in the Horace Tony mine, with good results. These mines are all on the quartz belt of Adam's hill, where there is an immense field for exploration.

In this neighborhood there has been
A Great Deal of Useless Work done, but as the formation is better understood than formerly, future explorations will be more profitable to the owners than in times past. Ore shipments to the Richmond furnaces are coming in steadily from the Dunderberg, Home Ticket, Connolly, Idaho, and Bay State mines. The last named, is of Newark District.

Twenty-four tons of heavy lead ore was shipped from the Original mine, on Silverado mountain, to the Richmond furnaces last week.

On the 25th ult. the miners of the

Pinto District

Held a meeting, the first for several years past. A general interest is re-awakening in this prom-

ising camp, and new claims are being recorded almost daily. M. B. Bartlett, a wide-awake business man of Eureka, has lately purchased a half interest in the Champion mine, which lies on the outskirts of the Pinto district, and will commence work on the ground within ten days from the present.

Mr. Bartlett, who has been merchandizing and dealing in real estate in Eureka for several years past, is also a man of many years' practical experience in mining. He was also one of the owners in the Geddez & Bertrand mine, Secret canyon, before it passed into the hands of Messrs. Gilmer and Salisbury. A new strike of very rich ore in this mine was reported a few days ago, which I do not doubt is true, and which, if true, will run the average of the ore up to a much higher grade than any that has been yet run through the mill. It is not generally known that, while Richard Berryman had the lease of the Geddez & Bertrand mine, he gouged out all of the best ore he could find in the 150 chamber, and left the low grade standing. This is true. It was also necessary, as until the Bertrand company built their mill and commenced reducing the low-grade ore by the leaching process, it was unprofitable to mine. Some good ore is being extracted from the Endeavor mine, Secret canyon, and the owners of the Water Jacket being thereby encouraged, will shortly commence work upon that mine. There will be a great deal of life in Secret Canyon district during the coming summer, and, as it adjoins Eureka district, we shall enjoy some of the benefits.

M. H. JOSEPH.

Not an alcoholic beverage, but a true and reliable family medicine, is Brown's Iron Bitters

VOLCANO, AMADOR COUNTY.—"A. M. H." writes us as follows: The rain gives the miners a chance to make something this spring, for they were idle all winter. We have some good gravel mines which pay well when we can get water; also some rich quartz mines in several localities, all over the county, which pay well. In Volcano, the Downs' mine is very rich, and the mill is crushing the best ore of the most of the time; also several other small leads that pay very well. The Tunnel company are making quite a large hole in the flat.

TRUE Temperance

Is not signing a pledge or taking a solemn oath that cannot be kept, because of the non-removal of the cause—liquor. The way to make a man temperate is to kill the desire for those dreadful artificial stimulants that carry so many bright intellects to premature graves, and desolation, strife and unhappiness into so many families.

It is a fact! BROWN'S IRON BITTERS, a true non-alcoholic tonic, made in Baltimore, Md., by the Brown Chemical Company, who are old druggists and in every particular reliable, will, by removing the craving appetite of the drunkard, and by curing the nervousness, weakness, and general ill health resulting from intemperance, do more to promote temperance, in the strictest sense than any other means now known.

It is a well authenticated fact that many medicines, especially 'bitters,' are nothing but cheap whiskey vilely concocted for use in local option countries. Such is not the case with BROWN'S IRON BITTERS. It is a medicine, a cure for weakness and decay in the nervous, muscular, and digestive organs of the body, producing good, rich blood, health and strength. Try one bottle. Price \$1.00.

New Firm.

A new firm in the paint, oil and glass trade has lately been established in this city, composed of W. D. O. Sullivan (son of C. D. O. Sullivan, vice-president of the Hibernia bank) and David Ravekes, for many years connected with the firm of Whittier, Fuller & Co. They have succeeded in obtaining several agencies for well known eastern firms, among which may be named Sherwin, Williams & Co., superfine oil and coach colors; Murphy & Co., varnishes and Germania white lead. The place of business of the new firm is at Nos. 220 and 222 California street.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

JOINT FOR SHEET METAL PIPE.

RE-ISSUE PATENT NO. 8,214 TO JOSEPH MOORE AND FRANCIS SMITH.

"The invention consists in connecting the meeting ends of the pipes firmly together and placing a band or tube around the outside of the meeting ends, which is larger in diameter than the pipes and which is long enough to extend a distance on each side of the joint and then filling the space between the outside band or tube and the pipe, with a packing of lead or other soft material, either by casting or tamping."—[Extract from specification of Patent.]

These joints have been tested for 8 years, and are undoubtedly the best joint made for sheet iron pipes—THE BEST AND CHEAPEST.

Any INFRINGEMENT will be PROSECUTED.

FRANCIS SMITH & CO.,
Manufacturers of Pipe of all Kinds,
130 BEALE ST., SAN FRANCISCO.

MECHANICAL ENGINEERING.

A first-class DESIGNER and MECHANICAL ENGINEER, capable of designing Steam Engines—stationary and marine—now holding a position of head draftsman in one of the leading Eastern engineering works, would be willing to take a similar position on the Pacific Coast under favorable circumstances. Address E. K., this office.

Mining Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company.

San Francisco, May 2, 1883.

At a meeting of the Board of Directors of the above-named Company, held this day, Dividend No. 54, of Twenty-five Cents (25c) per share, was declared, payable on SATURDAY, May 12, 1883, at the office in this city, or at the Farmers' Loan and Trust Company, in New York.

WM. WILLIS, Secretary.

OFFICE—Room No. 29 Nevada Block, No. 300 Montgomery street, San Francisco, California.

DIVIDEND NOTICE.

OFFICE OF THE

Silver King Mining Company.

San Francisco, May 1, 1883.

At a meeting of the Board of Directors of the above-named Company, held this day, a Dividend (No. 41) of Twenty-five Cents (25c) per share was declared, payable on TUESDAY, May 15, 1883, at the office of the Company, Room 19, No. 323 Montgomery Street, San Francisco, Cal. Transfer books will close May 9, 1883.

JOSEPH NASH, Secretary.

ASSESSMENT NOTICE.

Seaton Gold Mining Company.—Location of principal place of business, San Francisco, California; location of works, Drytown, Amador county, Cal. Notice is hereby given that at a meeting of the Board of Directors, held on the 10th day of April, 1883, an assessment (No. 2) of a vein and one-half cent (7½) per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Treasurer, A. Warner, at his office, No. 224 Kearny street, room 2, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 14th day of May, 1883, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 5th day of June, 1883, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

A. MARTIN, Secretary.
OFFICE—Room 6, 523 California street, San Francisco, California.

MILL & MINING MACHINERY.

F. A. HUNTINGTON,
No. 45 Fremont Street, San Francisco, Cal.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation. The wear and tear is nominal, and the construction so simple that any miner can put it up and run it, and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

CENTRIFUGAL ROLLER QUARTZ MILL!

After running one of these mills on the Whidden mine, in El Dorado county, over four months, and thoroughly testing its capacity and durability, I am prepared to offer it to the mining public, and claim for it the following advantages over the drop stamp mill:

1. The cost of same capacity is not more than one-half that of stamps.
2. Freight to mine one-fourth that of stamps.
3. Cost of erection at mine one-tenth that of stamps.
4. It runs with one-third the power per ton of ore crushed.
5. The wear is less than that of stamps.
6. The wearing parts are easily duplicated.
7. It has a much better discharge, and leaves the pulp in better condition for concentrating.
8. It is a better Amalgamator, saving fully nine-tenths of the gold in the mill; the balance can be saved on plates in the usual manner.
9. It is continually crushing; not like the stamp, using power to suspend it in air ninety-nine one-hundredths of the time, and the balance making a thundering noise, and accomplishing comparatively small results. It is as far in advance of the stamp mill as the present method of making flour with improved rolls is over the Indian's mode of crushing corn in a stone mortar.

F. A. HUNTINGTON, ESQ.—DEAR SIR: Your Centrifugal Roller Quartz Mill has run on the Whidden Gold Mining Company's property, at Shingle Springs, El Dorado county, Cal., about four months, and it did good and satisfactory work; a greater portion of gold remaining in the mill than in a stamp battery.

Mills Erected with all Appliances Complete. Capacity and Durability Guaranteed.

THE CONSUMERS' COMPANY.
VULCAN B B,
Black Glazed Powder,
In kegs and cases. The Best Low Grade Explosive in the market. Contains no Nitro Glycerine. Superior to Judson or any Black Powder made.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when ad-
 visable

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, or sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, riveted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstans, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

—FOR—

Galena Silver & Copper Ores.

The PACIFIC WATER JACKET SMELTERS embrace many features that are entirely new and of great practical utility, which are covered by letters patent.

No other furnaces can compare with these for durability and in capacity for uninterrupted work.

MORE THAN ONE HUNDRED of them are now running on the Pacific Coast, giving results never before obtained as regards continuous running, economy of fuel, grade and quality of bullion produced. We are prepared to demonstrate by facts the claims here made.

These Smelters are shipped in a complete state, requiring no brick or stone work, except that for the crucible, thus saving great expense and loss of time in construction.

Complete smelting plants made to order of any capacity and with all the improvements that experience has suggested as valuable in this class of machinery. Skilled and experienced smelters furnished when desired to superintend construction and running of furnaces. Estimates given upon application. Send for circular.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot, PARKE & LACY, 21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

-OR-
VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 23, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for. That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

EXCELSIOR BLASTING POWDER,

Manufactured by the

EXCELSIOR POWDER COMPANY.

This is no new, patent, non-explosive Safety Powder, but the Genuine Standard Nitro-Glycerine Powder, as safe to use and handle as any other Nitro-Glycerine Powder manufactured. The fumes and gases common in nitro-glycerine powders, are destroyed, and do not leave the miner with headache or nausea.

The powder is put up in cartridges of any size to suit the consumer, and is exploded in the same manner as all other high explosives; that is, by means of cap and fuse, or by electricity. It is not claimed for this powder that it is a non-explosive, or safer than other nitro-glycerine powder. All powder, and especially nitro-glycerine powder, should be handled carefully. The EXCELSIOR POWDER is as safe, and for strength far surpasses any other powder on the market. Address all orders to

HYDRAULIC GRAVEL ELEVATORS,

For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY.

Headwaters of the Arkansas.

On this page we give an engraving which shows Fremont Pass, at the headwaters of the Arkansas.

The Arkansas river rises in the Tennessee pass, nearly west of Mount Lincoln, in latitude 39° 21', and longitude 106° 19', and flows a little east of south for a distance of about eighty miles in a straight line, when it flexes to the east, and flows through a deep canyon in the granite, and emerges into the plains near Canyon City. Near the junction of the east branch of the Arkansas, the valley, with the terraces on either side, continues pretty regularly about five to eight miles in width, but gradually closes up again below Lake creek, though on

of this force has not been adequately understood, but the wider our range of observation, the greater is our conception of its power. We may safely assert that at some period comparatively modern, 10,000 or 15,000 feet of sedimentary beds extended uninterruptedly from the South Park across the interval now occupied by the Sawatch range, all of which but insignificant remnants, have been swept away, while a mass of the granite nucleus, of inconceivable dimensions, has also been removed. The general elevation of the Sawatch range for sixty to eighty miles is 13,000 to 14,000 feet above the sea at this time, and it is highly probable that hundreds, and perhaps thousands of feet have been removed from the summit.

In 1845, Fremont, at that time a Lieutenant in

New Dry Ore Separator.

In a new form of dry ore washer just patented through the MINING AND SCIENTIFIC PRESS Patent Agency by Patrick W. Reardon, of San Jose, the riffle box is suspended on spring-hangers from posts, so as to allow a vibration to be imparted to it. The riffle box is a three-sided, open ended frame, the bottom formed with riffles, and in such a manner as to present a short, steep face and a longer, gentle incline opposite. They resemble right-angle triangles lying upon the hypotenuse. Across the edge or face of each riffle, near its top, is a cleat for the heavier material to lodge against. A flat, adjustable cover fits down over the riffles, arranged so greater or less space can be

The riffle box has a downward inclination to the rear, as have the connecting pipe and wind box. This facilitates the operation of the device, which is as follows:

Ore is placed in the hopper, and its discharge regulated according to circumstances. The wind (a constant blast) is forced into the wind box, and, by reason of said box, spreads itself laterally, while contracting vertically, so that its force is equalized upon the body of ore in front of it, and its full effect delivered to drive it through the slot or aperture down through the connecting pipe into the riffle box. This box having a vibratory movement, tends to settle the ore so that the steady current of air passing along the upper portion of the box will carry off the light particles. If any of the

FREMONT PASS HEADWATERS OF THE ARKANSAS.

either side are vast deposits of the coarse drift material extending high up on the mountain sides, especially on the west side of the valley. The valley then gradually expands out and enlarges, about five to ten miles in width, for a distance of nearly forty miles.

On either side of the valley small streams flow into the main channel of the Arkansas, from the source to Canyon City. These streams usually have their origin at the very crest, or water-divide of the two ranges, and, in most instances, have cut their way through the solid mass to the main river. Many of these streams have numerous side branches, which have also carved out wonderful gorges near the crest of the mountains, giving to these mountain ranges a ruggedness that is almost inconceivable to one who has not actually explored them. It is in the study of these gorges that the geologist learns to appreciate the immense results of erosion in giving form to the rocky range of the West. Even yet the power

the Corps of Topographical Engineers, skirted the northern border for a short distance. He came up the Arkansas river, crossed the main divide at Tennessee pass, and traveled down Eagle river as far as the mouth of creek. Here he crossed the river and took the trail over to White river, which stream he followed down some distance, then crossed the country to the Green river, thence to Salt Lake City.

The pass was named after General Fremont. The Arkansas river is, next to the Missouri, the largest affluent of the Mississippi. It rises at the west-central part of Colorado, and its length is 2,170 miles. It is navigable for steamers 800 miles from its mouth, during nine months of the year.

Gold Mines in Oseola District are now presenting a better appearance than they have since their discovery.

CONSIDERABLE ore is being shipped to this city from Calico, San Bernardino county.

left between its under side and the riffles. A longitudinal vibration is imparted to the riffle box.

At one end of the riffle box is a large box of peculiar construction, which is stationary, but the connecting pipe between it and the riffle box is elastic, so the vibratory motion of the riffle box may be kept up.

Within the large box, which simply serves as a protector, is a wind box. This consists of a bottom and a top, let into the sides of the big box. Both bottom and top are inclined upwardly toward the front, though the top has the greater inclination, thus making the box lower at the rear than in front. The object of the peculiar construction is that the ore hopper may be placed in a good position so the ore or sand may fall through a slot, slowly, into the current of air passing through the wind box. The feed ore is regulated by suitable devices, and a blower is connected with the front end of the wind box.

heavier particles of ore are caught they will not be carried far before they are lodged below the cleats on the riffles.

In this device the air current is not employed for effecting the actual separation by driving the lighter portions up an incline, which proves too steep for the heavier portion, but for the purpose of providing a means for carrying off such lighter portions as may be kept within its influence by the vibration of the box. For this reason the upper portion of the passage through the box is smooth, and not tortuous, so that the wind will not be directed so much on the riffles and will leave the ore free to settle. The riffles are to prevent the heavy particles, which may be caught by the steady blast passing through above from being carried away. The air passage is diminished or regulated by adjusting the lid of the riffle box.

EXTENSIVE deposits of chloride and horn silver have been discovered in that section of the country lying between the Pecos River and the Rio Grande, Texas.

Inter-Oceanic Transit.

EDITORS PRESS:—I have for many years been interested in the question of inter-oceanic canals. Like most of those who have investigated the subject, my attention was first directed to the narrow Isthmus of Panama, of which I made a personal examination at my own expense, but of too limited a character to furnish much reliable data. I have since studied the data obtained by others and am of the opinion that to engineers having unlimited time and the resources of an empire at their command, the construction of a lockless tidal canal at Panama is possible, but that it is not possible ever to realize one per cent per annum upon the cost of construction. It was supposed that an immense business would be done by the Panama Railway, but ships will not go there for reasons so well understood by navigators that they need not be enlarged upon here. These reasons are permanent and cannot be removed by the construction of a canal. I refer to the calms that prevail off the coast of Panama and the currents of the Pacific ocean.

Reluctantly conceding the financial impracticability of the scheme, I examined the numerous surveys, reports, plans and estimates of all the other proposed routes in the hope of finding some one that I could believe in and advocate. Among them all the Nicaraguan is the only canal that seems to offer any inducement whatever for the investment of capital. This does. This I have believed in, advocated and hoped to see constructed.

Concerning this route, in one of his letters to Rear Admiral Ammen, U. S. N. (that of September, 1881), Sir E. J. Reed, K. C. B., late chief constructor of the British navy, and the highest authority in the world upon all matters pertaining to ships, writes as follows: "It seems to me that the advantage, as between the canals of Panama and Nicaragua, are all on the side of the latter from almost every point of view, while from the point of view of United States citizens, the preponderance of advantage in favor of the Nicaraguan route is enormous." I believe no disinterested engineer can dissent from this opinion, but he goes on to say, "As regards the comparative economy of transporting a ship's cargo by a canal or railway" (having reference to a ship railway), "I am inclined to think a railway would prove the more economical of the two."

The discussion of this opinion at this time in the present state of affairs is unnecessary, and I dismiss it with the remark that upon this point, among engineers and others best qualified to judge, there is diversity of opinion. After obtaining his concession from Mexico, Capt. Eads spent several months in Europe, and, on his return, made certain offers to our government under which American ships were to be transported at greatly reduced rates, at the same time saying, that if the United States did not wish to secure these advantages, he could make terms elsewhere.

The matter was referred to a committee, before whom Sir E. J. Reed testified strongly in favor of the railway, and added, under cross examination, that while it was, in his opinion, of vital importance to the United States to secure the special advantages of the concession made by Mexico, he anticipated no difficulty in securing ample English capital, if Eads would offer the same inducements to England he was then offering to the United States.

Our Government does not appear to have appreciated the significance of this statement drawn from Sir Edward, and the necessity for prompt action in favor of either railway or canal, nor that the lack of such action would greatly stimulate English capitalists and ship owners to secure the advantages of the railway and head off the construction of the canal under the belief that when it became apparent that the railway would first be in operation the idea of a canal would be abandoned. At any rate Congress failed to act in favor of either, and Eads troubled our Government no more. The press ceased to discuss the project, and his scheme soon seemed forgotten.

It is strange that those who knew the tireless energy of the man—that he had never failed to carry out any of his great undertakings; that had seen the written endorsement of his scheme by the leading engineers of Europe and America; that had heard him say that if he could not make terms with the United States he could with England, and heard this corroborated by Sir Edward Reed; that knew he had ceased to urge his scheme upon Congress and gone back to England; it is strange that they should have thought the scheme abandoned, and failed to realize the dangers of procrastination.

We now learn that an English syndicate is quietly engaged in the construction of this railway, with four parties in the field. Capt. Eads (when interrogated) says, "We expect to have the railway in operation within four years."

The stillness with which this enterprise has been conducted is ominous. Silently the work goes on without newspaper parade or blare of trumpets, and with the evident determination of securing to England the control of isthmian transit by acting while others are talking and getting the start of all. Truly "Britannia rules the wave," and she evidently intends to.

The Panama canal, if ever constructed, will

be finished at last by appealing to French pride and for the glory of France, to remain like a good many other things done for glory, a monument of folly. Whether completed or not matters little to the United States, save in a military sense, making her western coast more susceptible of attack from foreign nations.

If the advantages once offered us by Eads have passed irretrievably to England, the construction of the Nicaraguan canal will soon be to us a matter of necessity, admitting neither choice nor delay, and we will be forced in self-defense into that which done voluntarily and at the right time, would have secured for our vessels an advantage over all the shipping in the world; but, delayed until it can be delayed no longer, we will be driven to the expenditure after the investment has been shorn of more than half its value unless, indeed, as appearances indicate, it is the settled policy of our government to sweep our flag from the ocean.

Whatever our wishes and however humiliating to our national pride, owing to our own stupid procrastination, the ship railway will be open before any other route, and under the control and for the special benefit and continued supremacy of British shipping and to the honor and glory of England. This seems inevitable.

A. B. BOWERS, C. E.

San Francisco, May, 1883.

BE CAREFUL MINERS.—Continual association with a danger causes men to grow careless. Put a man in an Indian country, and let him get through a few weeks safely, and his vigilance will relax; put him in a mine, and what seems dangerous to him at first becomes, so far as any precautionary efforts of his are concerned, a safe condition of things. The dangers of mining in Arizona are not greater than elsewhere—not so great as in coal mines—but they are great enough to demand the closest attention of the miners themselves and the constant watchfulness of the superintendents and foremen. Rotten or worn ropes, imperfect splices, faulty timbering, broken ground, premature and delayed blasts, careless co-laborers, uncovered winzes that have been abandoned, all carry their dangers plainly written on them, to the eyes of the practical man, and still they are not avoided as sound sense and the law of self-preservation demand they should be. Miners themselves, knowing their danger, should adopt such precautions as the necessities of the case require. There are no "damages" sufficient to pay a man for the loss of his limbs, and in too many cases there should not be any.—*Silver Bell*.

ANTIMONY.—The Salt Lake *Tribune* says: The Antimony Reduction works at Antimony, on the heads of the Sevier, 120 miles from Juab, are completed, but some part of the machinery, we believe, for crushing, was badly chosen, and it will require a month, perhaps, to replace it. That done, the output of the property promises to be steady, beginning, perhaps, at two or three tons of pure metal per day, and increasing as the demand shall justify. Mr. Clark, of St. Louis, antimony expert, has recently returned from an inspection of the property, and he said to our reporter that he was very well pleased with it. The visit is perhaps likely to result in the infusion of new blood into the concern, although it has proceeded, we should say, with fair speed and average judgment, from its inception. For Utah to supply this country, and possibly foreign countries, with antimony, will be a fine feather in her cap—a good advertisement. It will, without doubt, prove profitable to its projectors. Mr. Anthony Godbe expects it to pay, after getting in full operation, five per cent per annum on a million.

FURNACES BETTER THAN MILLS.—If the Raymond & Ely and Meadow Valley Companies had erected furnaces for the reduction of their ores, instead of mills, they would have been over a million dollars better off. We are led to reason thus, says the *Pioche Record*, partly from the rich bonanza that the Smelting Company is now reaping in Bullionville from the reduction of the tailings of said ores—they having realized some \$300,000 thus far with a twenty ton furnace—and partly from the enormous amount of quicksilver that was wasted by the mill process. It is very true a furnace was erected in Pioche when that camp first came into prominence, but the art of reducing ores by the smelting process was then in its infancy, and the venture could not prove otherwise than a failure.

The citizens of the new county of Garfield, in the western part of Colorado, which was formed by the last Legislature on account of the new carbonate discoveries, have petitioned Secretary Teller to allow the United States troops to remain there for their protection against the Ute Indians.

LIGHTNING passed down a shaft in a coal mine at Wilkesbarre a few days ago, and caused an explosion of gas.

THERE have been forty-five mining districts so far organized in Yavapai county, Arizona. The Walker District is the oldest.

The Point Sal gold mines, says the *San Luis Tribune*, are yielding from one to four dollars per day. The gold is very fine and mingled with black sand, which is found four to eight feet in depth along the beach.

MANY prospectors are traveling toward the new mining district on the Colorado Desert, called the "Poorman's." Several locations have been made there already.

Mining Property.

The troubles in Europe are forcing millions and tens of millions of English capital into this country and Mexico. The rage for purchasing cattle ranches and cattle seems to have become almost a passion with English and Scotch capitalists. It is said that \$200,000,000 have been invested in that kind of property within the past eighteen months. We read two days ago of the transfer of a railroad system in Mexico to an English syndicate, and generally the tendency of money is toward the land which offers the best protection for it. People who have mines and who have not the means to operate them and build reduction works, should make a note of the above facts, and should take advantage of the desire which rages in Great Britain for investments in America.

If mines have a black eye in England now, it is due in almost all, if not all cases, to the rascality of English middle men. They secure an option on a property for a certain sum, and unload it on their countrymen for three times that sum. To do it they make false representations and present false reports; they cause the English company to order five times the machinery that the mine will bear, and the result is disappointment and loss. This fact ought to be understood in England by this time. To sell a mine a man should have an exact report of its condition, maps to make it plain, copies of assays, and samples of every species of ore which the mine contains, with all other important facts. Then the sum asked should be reasonable, and the facts should be guaranteed by the seller, and the sale should be contingent upon the property fully bearing out the description. Of course, it requires some ability and influence to reach the ears of foreign capitalists, but it can be done, and were a few mines disposed of in this way, more sales would follow, for a good mine is better than a cattle ranch after all, and all that is required to make them popular with real purchasers, is to lay real facts before them.—*Salt Lake Tribune*.

VIBRATION OF SOLID BODIES IN CONTACT WITH LIQUIDS.—Recent investigations as to the effect of liquids contained in glass vessels upon the pitch of the sounds produced when the latter are set in vibration have yielded the following results: 1. The geometrical lowering in pitch (ratio of number of vibrations), produced by a liquid contained in a cylindrical glass completely filled by it is less in proportion as the pitch of the empty glass is higher. 2. The arithmetical lowering of pitch with a cylindrical glass of mean pitch is approximately proportional to the reciprocal of the square root of the number of vibrations of the empty glass. 3. The lowering of pitch, when the glass is completely filled is not noticeably dependent on its height. 4. The geometrical lowering of pitch produced in cylindrical glasses of different widths is greater in proportion as the glass is narrower. 5. The arithmetical lowering of pitch with cylinders of different widths is inversely as the square root of the width. 6. The arithmetical change of pitch is inversely proportional to the square root of the number of wave lengths of the sound given by the empty glass contained between the walls and axis of the cylinder. 7. The lowering of pitch is greater as the density of the liquid is greater. 8. It is greater in proportion as the compressibility of the liquid is less.

THE PARADISE MINES.—J. V. McCurdy, from Paradise, says there is considerable prospecting carried on in the district. The force in the Bullion has been increased, and the mine looks well. Nick Frayer is hauling ore from the Live Yankee to the mill. Branan & Marcott have about ten tons of ore sacked at the Rattler that will average about \$1,000 to the ton. Choate & Metille are driving a tunnel to their lead, from which they have taken ore that worked \$280 to the ton at the Bullion mill. Matt Henderson, who had a lease of the Paradise mine at one time, and made as high as \$500 a day clear of all expenses, is back in the district prospecting. He has discovered a ledge on the east side of Spring canyon, which he thinks is the same as the Paradise.—*Silver State*.

The gold belt in Georgia extends from Virginia and North Carolina to Florida and Alabama. It is from 120 to 140 miles wide. Thousands of people support themselves by working in the mines. In one place alone, in Lumpkin county, twenty-six stamp mills are working, each of which employs five to fifty men. Some of these gold mines have been worked for years, and in places the earth is dug away sixty feet. Some of it is very rich in ore. Four hundred acres were sold some time ago for \$5,000,000 to English capitalists. All the mining is done by wealthy capitalists and there are few poor men in the belt. It is a busy place. Good wages are paid and the men are industrious and sober. People are flocking there from the far West, and even from Australia and Mexico.

PHOTOGRAPHY now plays an important part in book illustration, and many books are published which might be called collections of photographs with descriptive letter-press. One recently published by William Patterson, of Edinburgh, under the title of "The Castles and Mansions of the Three Lothians," contains 103 photographs, each about 7½x5.

The Postal Changes.

Rates of Letter Postage Under the New Law—The Proposed Postal Notes.

On and after October 1, 1883, letter postage will be two cents for each half ounce, or fractional part thereof, between all points in the United States. The rate will then be the same as drop letters and all others. No changes have been made in rates on other classes of matter.

On and after July 1, 1883, you can obtain at any money order office, postal notes in sums of \$5 and under by paying a fee of three cents. These notes will be made payable to bearer without corresponding advices. They will be payable at any money order office within three months of the date of issue. After the lapse of that time the holder can obtain the par value only by applying to the Postoffice Department at Washington.

On and after July 1, 1883, you can obtain a postal order for as large a sum as \$100. The present limit is \$50. The fees on and after that date for orders will be as follows:

Not exceeding \$10.....	8 cents.
From \$10 to \$15.....	10 cents.
From 15 to 20.....	15 cents.
From 20 to 30.....	20 cents.
From 30 to 40.....	25 cents.
From 40 to 50.....	30 cents.
From 50 to 60.....	35 cents.
From 60 to 70.....	40 cents.
From 70 to 80.....	45 cents.
From 80 to 100.....	45 cents.

The postal notes will, no doubt, be found more convenient in one respect than the fractional paper currency was, since they can be obtained for any number of cents under \$5. There will also be less liability to loss, by theft, than there was when fractional notes were used for transmission through the mails, especially if the department uses judgment in prescribing the size and form of the notes, and in selecting the paper on which they are to be printed. On the other hand they will be less convenient, in that they can only be obtained at money order offices at a considerable sacrifice of time, especially in large cities. It will be observed that after the first of October the cost of sending any sum under \$5 postal note will be 5 cents—2 cents postage and 3 cents fee.

TOM FITCH, ex-Congressman from Nevada, has invented a process for leaching copper ores, which, it is claimed, will revolutionize the working of low grade ores. We seem to have heard of such claim having been made before in this connection.

Recent Contributions to the California State Mining Bureau.

MECHANICAL PROGRESS.

Valuable Improvement in the Manufacture of Refined Tool Steel.

This invention relates to a new method of manufacturing steel in what is commonly known as the "open-hearth"—that is to say in a Siemens or equivalent furnace—and has for its principal object the production of high grades of steel suitable for tools, etc., for which the more expensive crucible steel has heretofore necessarily been used. In the ordinary method of making steel by the open-hearth process, a bath of molten cast iron is first prepared, and the process consists of decarburizing the molten metal by introducing into this bath wrought iron or other iron low in carbon, or ore, for the purpose of decarburizing the melted metal, which is effected by the melting of a sufficient quantity of wrought iron in the pig iron to reduce the percentage of carbon in the whole mass sufficiently to form steel, the melted product being finally recarburized by the addition of ferro-manganese or spiegeleisen.

It has also been proposed, though we believe without success, to reduce iron ore by decarburization, and to melt it by the aid of carbon in the mouth of the melting furnace, to form a bath of highly carburized molten metal, into which a further charge of reduced ore or blooms may be introduced, which are melted in the bath has been prepared, for the purpose of decarburizing the bath.

The invention, however, of which we are writing, differs widely from both of these in that it is a carburizing and not a decarburizing process, and consists in melting Swedish iron of the finest grades or pure charcoal blooms or steel low in carbon, on the surface of a charge of carbon in an open-hearth furnace, so that the melting metal may trickle down through the carbon, and thereby become carburized to the required degree to form steel. This process avoids the impurities always present in steel produced by the employment of pig iron, and enables it to produce a high grade of refined tool steel suitable for the best purposes, and fully equal in quality to the best English and American brands, which we believe cannot be accomplished by any of the previously-known processes. This valuable patent is used exclusively by the Bolton Steel Company, of Canton, N. H., where it has been in successful practice for several years, producing a quality of steel remarkable both for its purity and uniformity.—*Age of Steel.*

STEEL VS. IRON.—In advocating the use of high qualities of steel, and enumerating the advantages to be gained by employing it, says Percival Roberts, Jr., the fact is frequently lost sight of that this superior metal is made from the highest grade of pig, obtained with the greatest care from the purest ores, and that the succeeding processes are worked out with the aid of the most improved plant. The metal is followed through all details of manipulation with the most thorough inspection and rigid chemical and mechanical tests.

Material thus obtained is compared with wrought iron made from anything and everything. No chemist mixes the charge or analyzes the product, but a puddler is left to guard the interests at the most vital stage of the process. It is his aim to produce the greatest weight, with the least labor, in as short a time as possible, and with such work no one can blame him. It is not astonishing that under such conditions iron is so much inferior in its physical qualities to steel. Even taking the same grade of pig metal for the manufacture of wrought iron as is now used for steel, the mild grades of the latter suitable for structural purposes, will, no doubt, give higher results by mechanical tests, but the difference between the two will not be as great as many are apt to think.

IN THE NEW ALLOY.—In the new alloy on copper, iron and zinc, considerable difficulty has been experienced in securing a uniform admixture of the iron. A London experimenter said to have overcome this by his method of introducing the iron into the mixture of zinc and copper. When ordinary wrought iron is introduced into molten zinc the latter readily dissolves or absorbs the former. The exact point of saturation or the proportion dissolved or absorbed varies with the temperature at which the molten zinc is maintained during the process, and it is by carefully ascertaining and controlling this temperature that a perfectly uniform product has been obtained. The metal thus produced, and to which the name of Delta metal has been given, is stated to be as much superior to brass as phosphor-bronze is to gun metal, or as steel is to iron. It possesses great strength and toughness, and samples cast in and give a breaking strain of twenty-two tons per square inch.

AMERICAN LOCOMOTIVES AND CARS.—It is said that from ninety-five to ninety-eight per cent of all of the railroad locomotives in use in British colonies were manufactured in the United States, and that all of the continental European countries have their roads equipped to a greater or less extent from the same source. Within the last ten years the exportation of railroad locomotives from the United States has aggregated some \$12,000,000 and the passenger coaches \$40,000,000.

Progress of Electrical Invention.

The *Age of Steel* remarks that, notwithstanding electricity has made rapid strides as a human, its progress as a motor has been slow and laborious. It is true that electric railroads are in operation in France, Germany, England, Ireland, Austria and in this country, but it is equally true that their economy, compared with the ordinary railroad with its steam motor, has not been demonstrated; on the contrary, we believe experiments have shown that the operating expenses of an electric railroad are considerably in excess of those of any ordinary railroad. But whether this will always be the case is a question upon which, as yet, it is not safe to hazard an opinion. Until within very recent years, electricity was unknown to the public except in connection with atmospheric disturbances of the "thunder and lightning" order; and in the scientific world it was best understood by chemists. To-day, however, a class of young men are growing up who are making the study of it a specialty, and newspapers are being established in every civilized country in the interest of electricity and electricians. Under such circumstances it is not unreasonable to assume that electrical invention will spread far beyond its present limits—and mayhays the economy which is so eagerly sought for in the utilization of the fluid as a motor will be found. It is too early to condemn its employment as a motor let us wait and watch and wonder.

Prof. Henry Morton, of the Stevens Institute of Technology, in New York, in an address delivered there a few days ago made the assertion, the truth of which he demonstrated by experiments, that by a very simple contrivance, and at a very slight expense, electricity as a motive power could be used economically, not merely to propel street cars, but to drive all sorts of machinery. He stated that the energy that might be stored in a box in size equivalent to a cubic foot, was sufficient to drive a loaded street car from one end of that city to the other.

MOLDING PATTERNS.—A writer in the *Mechanical World* says: For patterns which have to be repeatedly molded in damp sand it is advantageous to mix with the glue some good thin drying oil in the proportion of about one of oil to four or five of water. The oil should be added to the glue and well stirred in while it is hot. (Glue so made is scarcely affected by moisture and makes a good sound joint, although it is not quite so strong as glue mixed in the ordinary way. Good glue should be clear, transparent and of a light brown color, and the best way to make it up is to break it up into small pieces and soak it for twelve hours or so in as much water as will cover it, and melt it in an ordinary glue pot, letting it simmer gently for one or two hours. As I have assumed that the glue was required for pattern making, I should state that it is always advisable—no matter what kind of glue is made use of—in order to thoroughly protect the patterns from moisture, to coat them with good oil paint.

THE STEAM ENGINE.—Taking the best types of engines of to-day as a starting point, we must depart in the following directions: We do not particularly need to increase the efficiency of the boiler as an evaporator, but we must increase its ability to withstand pressure without increasing its cost. We must decrease the friction of the engine and of the machinery of transmission to the point where the useful work is delivered. We must produce better vacuums in the condenser, and diminish its cost. We must diminish the cost of the engine. We must diminish the cost of the attendance on engines, boilers and machinery, and of lubrication. We must increase the durability of engines, boilers and machinery. Coal is too cheap even now to admit of increased economy of it at the cost of increased outlay plant and attendance.

AN EXPERT WORKMAN.—A Connecticut paper tells of a machinist in that State who is so expert a workman that he has cut an ordinary sewing machine needle in two lengthwise, drilled holes lengthwise through the halves and remitted them so that the line of their division is not observable; all of which indicates a steady hand, an observant eye, nice workmanship and good and proper tools. That man ought to command high wages from manufacturers of delicate apparatus.

TRACTION INCREASES TESTS.—A series of tests were recently made in St. Louis with M. A. Dees' traction increaser, which demonstrated, according to the report of the testing committee, that 16,800 pounds had been added to the weight upon the driving wheels of the locomotive to which the device had been attached. The device is constructed so that it can be thrown "off" or "on" at pleasure, enabling the engine to throw a part of the weight of the tender upon the driving wheels of the engine at any time he may need it.

The largest rolling mill shears in the U. S. were set up on the 3d inst. by the Judson Manufacturing Co. at Oakland, in this State. These shears were manufactured in the Judson works. The weight is eighteen tons, and the shears can cut a bar of iron four and a half inches square. Tack plates are now rolling out at the works, and in a few days large quantities of merchants' bar iron will be rolled.

SCIENTIFIC PROGRESS.

Meteoric Iron.

One of two blocks of meteoric iron in the possession of the British Museum, and found in Victoria, Australia, in 1854, was recently studied from a chemical and mineralogical point of view by Dr. W. Flight, of that museum. At the time of finding the mass, which weighs somewhat over three tons, only a small portion projected along the soil, the remaining portion being imbedded in tertiary sandstone overlying basalt. Dr. Flight states that the entire mass consists of metallic minerals and is destitute of silicates. In the course of the analysis the iron was found to contain numerous minute brittle, strongly magnetic, apparently square, prisms, which form about one per cent of the mass. These prisms were slowly and with difficulty acted upon by hydrochloric acid, but readily dissolved in nitric acid. Scales were observed lying on the faces and between the plates of iron crystals, being in the form of equilateral triangles, and having the thickness of stout writing paper; they were, moreover, pliant, strongly magnetic, and of a pure white color. Analysis showed the mass to contain 70.138 per cent of iron and 29.744 per cent of nickel, and Dr. Flight proposed for it the name Edmondsonite. The analysis of a brittle magnetic powder, which easily dissolved in nitric acid, gave the formula (Fe₂ Ni₁₇ P. A large brass-colored, oblique crystal, showing perfect basal cleavage, dissolved readily in *aqua regia*, but was only slowly acted upon by hydrochloric or nitric acid alone, and gave, on analysis, the formula (Fe₉ Ni₂) P₂. Another crystal which was found was apparently a square prism, having brilliant metallic sides, with a dark, almost black, center. Its analysis gave the formula (Fe₇ Ni₂₈ P. Graphite occurred occasionally in this meteorite, both in nodules and in plates. The iron was also examined for occluded gases, and carbonic acid, carbonic oxide, hydrogen, nitrogen and marsh gases were found.

THE ARTIFICIAL AURORA BOREALIS.—Some additional points of interest in regard to the artificial aurora, to those we gave in this column last week, will be found in the following paragraph from the *Scientific American*: Laboratory experiments have been frequently resorted to to produce the aurora in miniature, and the resemblance to the original has been extremely close, but an artificial aurora on a large scale and with no electrical machinery has lately been effected by Prof. Lemstrom. He selected a station just within the Arctic circle, in North Finland, where there were two mountains close together and having altitudes of 2,600 and 3,600 feet. In accordance with the well-known fact that electricity gathers upon points, two hills having clearly defined conical summits were selected. He believed that aurora was the result of an endeavor on the part of certain forces to establish an equilibrium, and assumed that electricity was passing from one hill top to the other. Reasoning that if by any means this interchange could be hastened the effect would become visible, the summits were connected with their bases by a network of copper to serve as a conductor. Immediately an arch of the aurora appeared, estimated to be at least 360 feet above the top. An examination of the currents produced in the wires showed them to be positive. The spectroscopic clearly revealed the well-known lines of the aurora. Although the display was only of short duration, there could be no doubt of its genuineness or of the success of the experiment.

AN INTERNAL MITE IN FOWLS.—Prof. Thos. Taylor, Microscopist of the Department of Agriculture, had occasion recently to dissect a sick chicken, and he found that all parts of the lungs, the brouchie, and the linings of the thorax and abdominal cavities were covered more or less thickly with a mite. An examination we were requested to make showed it to be in all respects identical with *Cytolichus sarcopoides*, Megnin. This parasite is known in Europe to inhabit the air passages of gallinaceous birds, giving the transparent and membranous linings of these passages the appearance of gold beater's skin speckled with flour. It is likewise found in the bronchial tubes and their divisions, and even in the bones with which the air sacs communicate. Megnin believes that while the mite may be extremely numerous, so as to cause mucous irritation and induce asphyxia and congestion by obstruction of the bronchia, and that birds may thus die, yet it is incapable of causing, as Gerlach and Zundel believe, enteritis or inflammation of the peritoneum.

FOOD FOR THOUGHT.—Mr. Richard Proctor makes a very curious suggestion in a recent number of his paper, to the effect that the spreading of so large a quantity of iron upon the surface of the earth, as modern sciences is doing, is likely, in the future, to exercise a very decided influence of its own upon electric currents and magnetic storms, and in this way to exercise a very material meteorological influence. The network of railways and the substitution of iron for wood all over the country is going on steadily and in a rapidly increasing ratio. Even the Western prairies are being netted in all directions by wire fences, and in calling attention to this fact Mr. Proctor thinks that here is a problem that science will shortly be called upon to solve.

Thorium.

The metal thorium, the existence of which was so long doubted by chemists, has recently been isolated and its properties carefully studied by Mr. Nilson. The metal was first discovered by the eminent Swedish chemist, Berzelius, who detected a new earth in a Norwegian mineral which he called "thorite." The earth was called "thoria," from which is derived the name of the metal, thorium. Nilson's investigations have modified to some extent the statement of the properties of this rare metal as generally laid down in text books. He succeeded in isolating it by reducing the double chloride of potassium and thorium by treatment with dry chloride of sodium and metallic sodium. This mixture was heated to a low red heat in a wrought-iron cylinder furnished with a piston to make it air-tight. By this means the metal was obtained in a gray, lustrous powder, which under the microscope was seen to be composed of six-sided lamellar crystals. The metal was found to be unaffected in the air, even when heated to a temperature of from 212 to 248 F. Heated to nearly redness, however, it burns with a bright light to snow-white oxide. Burned in chlorine gas it forms a white sublimable chloride, with the evolution of heat and light. It is unaffected by water and by hydrated alkalis. Diluted sulphuric or nitric acid is stated to cause a feeble evolution of hydrogen gas. Concentrated sulphuric acid causes a slow formation of sulphurous acid. Dilute hydrochloric acid attacks and dissolves the metal readily, as does likewise *aqua regia*. Thorium has a specific gravity of 10.99 to 11.01. It is tetravalent, and its atomic weight is 232.40.

GENESIS OF A NEW WORLD.—On a beautiful summer's night, August 22, 1794, Jerome and Lefrancais de Lelande noticed a star in Aquarius, which they estimated of the seven and one-half magnitude. Six years later they thought it of the eighth magnitude. In appearance it resembles a star which is not exactly in the focus of the telescope. Herschel had observed it in September, 1782, and recorded it as an admirable planetary nebula, very brilliant, small, and elliptical. Lord Rose and Lassell perceived that it was surrounded by a ring, which gives it somewhat the appearance of Saturn. The spectroscopic observations of Huggins indicate that it is a gaseous mass, in which nitrogen and hydrogen predominate. Most of the other planetary and annular nebulae give similar results. In 1871 and 1872 Brunnow, the Irish Astronomer Royal, measured its parallax and concluded that its distance is more than 404,000 times as great as that of the sun, and its diameter is probably greater than that of the entire solar system. This would make its volume more than 338,896,800,000,000,000 times as great as that of the earth. We have thus, before our eyes a new system, which is probably undergoing the process of condensation through which our sun and its attendant planets passed hundreds of millions of years ago.—*L'Astronomie.*

ON THE AMMONIA IN THE AIR AND IN RAIN, ETC., AT GREAT HEIGHTS.—It has long been known that the small traces of ammonia in the air are carried down to the soil by meteoric precipitates, and Schlosing has shown that it is fixed directly by the oxidizing action of the soil and leaves. In connection with these investigations he also called attention to the sea as the great reservoir which supplied the air with ammonia. He devised an ingenious method, which enabled him to operate on large quantities of air, and with it he examined the currents of the air circulating near the ground. Recently Muntz and Auber (*Comptes Rendus*, xcv., 788) have been estimating the amount of ammonia in the air on the top of Pic du Midi, which is 2,877 meters (nearly two miles) above the level of the sea. The tests were made morning and evening in a laboratory especially erected for the purpose. The average was 1.35 milligrammes in 100 cubic meters. These numbers, although so extremely small, do not differ perceptibly from those obtained at the earth's surface. They also made thirteen analyses of rain, seven of snow, and five of fog. In rain water they found between 0.34 and 0.80 milligramme per liter, in fog 0.19 to 0.64 milligramme, and in snow 0.06 to 0.14 milligramme of ammonia per liter.

VIBRATORY MOVEMENT OF BELLS.—M. Mathien, a French experimenter, has recently studied the vibrations of bells, considering the case of an ordinary bell in which the thickness in any meridian increases from summit to base. The essential difference between the vibratory movement of a bell and that of a plane plate is that, while in the latter the longitudinal or tangential movement and the transverse movement are given by independent equations, and the normal and tangential motions in the former are given by three equations which are not independent. The pitch of the notes of a bell does not change if the thickness varies in the same relation throughout every part, since the terms depending on the square of the thickness may be neglected, at least for the graver partials. It is impossible to construct a bell so that it shall vibrate only normally, and with a hammer the tangential vibrations are of the same order as the normal vibrations. A purely tangential motion can be realized only with a spherical bell of constant thickness.

NEVADA PLACER MINES.—The *Pioche Record* of last Saturday says: Water is to be brought into the Osecola gold mines this season. Messrs. Godbe and Hampton, while at Bullionville the other day, who own 520 acres of patented placer ground in Osecola district, said that they had completed arrangements for bringing water into that district. They had not yet decided as to whether they would flume the water or bring it in with pipes, but thought they would pipe it. This will make Osecola bloom with industry, and the gold that the rich gravel will yield will pay handsome returns to the enterprising gentlemen for their trouble and labor. The money for carrying out this project was advanced by the late Trenor W. Park.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK.—Amador *Ledger*, May 12: A clean-up has been made at the Mahoney mine, and the hearts of the boys will be made glad to-morrow with a pay-day. The repairing of the shaft of the Amador Con. is completed, and sinking operations were commenced on Friday. The intention, I am told, is to sink 300 ft before stopping, and this work will take about all summer.

El Dorado.

ENCOURAGED MINERS.—*Mt. Democrat*, May 10: At the Spring Tunnel mine, Georgetown township, which is being worked by Messrs. Hewett and Savage of Oakland, they cleaned up last week after a run of six days, with results so satisfactory that the owners have determined to run night and day henceforth.

ANOTHER MINING CONTRACT.—A contract has been let for sinking 50 ft deeper on the Pleasant Valley ledge, and a number of experienced Cornish miners have come over from Plymouth, Amador county, to do the work. This is a large ledge—from five to eight ft, from its first discovery and in all of its workings it has turned out uniformly high grade ore, and has constantly improved as greater depths have been reached. All old miners who have examined it concur in the opinion that the Pleasant Valley mine has a long and prosperous career in store.

THE EUREKA MINE.—E. E. Cheek has charge of the Eureka mine, located in the suburbs of Georgetown, and is about to erect a mill which will have a capacity for crushing 60 tons per day. This mill has been built at the East, and is now on its way out here. Mr. Cheek has lately discovered a ledge running parallel with the main ledge of the Eureka, which from present indications is exceedingly rich.

A PAYING MINE.—At the Josephine mine, Georgetown township, the mill is being run day and night on high-grade ore, and it is now apparent that they will have to add 10 more stamps to the 10 now at work.

WONDERFULLY RICH ORE.—At Adlerson's store may be seen a number of large samples of the ore recently struck in the Mount Hope mine, near Grizzly Flat, to which strike was made brief reference in our last issue. It is unlike any ore we have seen from any other lode in the county. It is all a mineral of an exceedingly dark lead color. It is lined with small pieces of iron an inch thick, of tellurium, imbedded in sulphurets. Test assays made in San Francisco have yielded from \$180 to \$285 per ton. This ore was struck on the 200 level, about 60 ft from the Flag Staff line. They have explored it for 20 and 30 ft, sufficient to demonstrate that there is a large body of it. Of course this ore cannot be worked by the ordinary wet process without enormous waste, as the gold is in exceedingly fine particles, closely combined with the tellurium and sulphurets, and a large proportion—probably nine-tenths—would float off. Therefore Supt. Lyon must erect smelting works or ship his ore to some point where it can be smelted, or content himself with but a small portion of the gold it contains.

Invo.

THE KEYNOT. - Inyo *Independent*, May 12: Assessor Irwin has returned from an official visit to the Beveridge country. He says the Keynot mine is yielding plenty of free gold ore, which works from \$35 to \$40 per ton, at the new Lasky mill. The yield of gold bullion is from \$1,000 to \$1,200 per week. The McEvoy mill is idle for the present.

Mono

ILLINOIS.—Homer *Mining Index*, May 10: This claim is situated on the mountain side west of Mono Lake, and has heretofore been briefly alluded to. It is owned and is being developed by Wm. L. Callahan and E. F. Isbell. A surface crosscut 14 feet in depth shows a strong vein of two feet of free gold ore inclosed in black slate country rock, with some porphyry casings. The ore yields handsomely in fine gold on being crushed and panned. The owners have a torrent of water crossing the ground, and a dense forest of nut pine timber.

GRIZLY.—The tunnel in the Grizzly, situated a few hundred yards above the May Lundy mill, has followed in the vein a distance of 155 feet, at which point a crosscut six feet to the eastward fails to show the hanging wall, though it has reached a heavy clay seam rich in gold. Some of the ore encountered in the crosscut is also very rich in free and fine gold. The tunnel is still 15 feet short of the face of the bluff, where it is confidently believed the vein will assume greater solidity, but is being vigorously pushed.

Nevada.

QUARTZ MINES.—*Nevada Transcript*, May 16: The Nevada City mine is looking better now than ever before. They are doing a large amount of dead work, and in fact their aim seems to have been to thoroughly open the mine before attempting to make it a bullion producer, which they might do at any time were they so disposed. They have now reached the 600 ft. level and there they found a splendid three foot ledge, which looks as well as any

San Bernardino.

MAMMOTH.—*Calico Print*, May 12: The work in this mine has been partially suspended, the force of men being employed in opening up the road in Wall street canyon, which has now been completed to the mine. A tramway and car track 600 feet long extends from a dump near the lower tunnel to a 200-ton ore bin in the canyon below. Preparations are being made to extract a great deal of ore. The force of men will be increased; and a large quantity of ore will be taken out and shipped to the mill every day. Some good ore is being taken out, and the prospects of the mine are as bright as ever.

SILVER KING.—Work in this mine is still progressing, and the yield of bullion is increasing, owing, to a certain extent, to a more careful assortment of the ore. Another ore bin that will hold 200 tons has been built a short distance from the superintendent's office. Mr. Al. Waitt has been appointed foreman of the mine.

KEARSAGE.—Three men are at work on this mine and judging from the character of the ore taken out it is a valuable piece of property that is destined to

Mining Share Market.

Mining stocks have been quite active for a few days and the market has a firmer tone than has been noticeable for some time past. This is probably due to reports from the Comstock, where, though nothing definite has been found, there seems to be a general feeling of favorable expectancy. The *Enterprise* says that at the north end indications are very flattering. At several points one might be taken out, but there are those who are not in favor of doing anything until the time arrives when a "very big thing" can be done. Down in the middle mines there is great activity in all operations. With the new air they will get from the 2400 level through the winze they will be able to do some wonderful work. The same connection will be of great use to the Savage, Hale & Norcross, Chollar and other mining companies in that neighborhood.

At the south end things are looking up well, and in another week or two some changes of great importance will be seen.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports :

Hanauer, May 8th, \$1,890; Al'cee, 8th, \$28,028; Horn Silver, 8th, \$15,000; Bullionville, 8th, \$2,925; Ontario, 8th, \$9,183; Hanauer, 9th, \$2,000; Horn Silver, 9th, \$9,000; Ontario, 9th, \$4,900; Horn Silver, 10th, \$6,000; Bullionville, 10th, \$3,020; Ontario, 10th, \$4,737; Horn Silver, 11th, \$5,000; Bullionville, 11th, \$2,523; Ontario, 11th, \$4,456; Moulton, 13th, \$4,956; Ontario, 13th, \$4,454; Mt. Diablo, 7th, \$7,650; Northern Belle, 7th, \$7,456; Standard Con., 7th, \$16,743; Odessa, 10th, \$2,910; Alhambra Con., 10th, \$1,802; Mt. Diablo, 10th, \$5,077; Head Center, 11th, \$8,800; Standard, 7th, \$14,724; Northern Belle, 10th, \$6,485; Navejo, 14th, \$15,000; Gold Hill, 12th, \$9,000; Con Wyoming, 15th, \$9 337; Bodie Union, 15th, \$1,830; Contention, 12th, \$46,000; Bodie Con., 15th, \$5,463.

SOMEBODY owning a mine in Mexico, telegraphed to Greenville, Plumas county, in this State, for five miners, and the men have started for their destination. This seems a long way to send for miners, but good men are always in demand.

yield its owners a handsome fortune each. A shaft is down 25 ft from which ore of a high-grade is being extracted. The ore is carefully assorted, and the four or five tons sacked on the dump assays on an average up in the hundreds.

INVISIBLE.—This mine is making a fine record. Ever since it was opened it has netted excellent returns. There are six men at work in the mine, and the tunnel and cuts are showing up beautifully. Eleven tons of ore were taken to the Silver Odessa mill at Hawley's station within the last week. John Lane is now foreman of the mine.

BORAX.—The excitement in prospecting for borax has not decreased. Monuments are again springing up all over vacant lands like office seekers just before election. Men start out from front on a "dog trot," leaving in their wake rows of monuments, and do not slacken their pace until the shades of night prevent further operations. Inside of a couple of days two men located 66 claims, and one was located at that. If men work the silver mines with the same energy that they cover the country with monuments, the camp would soon be booming. Judging from reports, some fine borax prospects have been located, and some more sales are about to be made. F. M. Neel is about to receive \$2,000 for some property, and H. B. Stevens has bonded some claims for \$8,000. It is reported that reduction works will be put up to prepare the borax for the market. The mines are so near the railroad that the expense of extracting and shipping it will be considerably less than that which attends the business now monopolized by Cadenan & Co. While searching for borax and analyzing the same, other minerals are found. Salt, alum, Glauber's salts, potash, soda, gypsum, lime and several other substances are found, some of which may prove to be very valuable when it is determined, by experts, the uses to which they can be put.

Sierra.
THE RICH STRIKE IN SAILOR RAVINE. *Sierra Tribune, May 11:* In last week's issue we mentioned the fact that an important find had been made in the old Page mine, located in Sailor ravine, two miles north of this place. The Page ledge was taken up by Messrs. Baker & Cowden three years ago. Previous to that time it had been located by parties who took out several thousand dollars at a depth of only 15 ft from the surface. After locating the mine, Cowden & Baker prospected along the croppings 1200 ft and found a fine prospect the whole distance. A tunnel was then started and run in 20 ft on the vein. The ledge at this point is two and a half feet wide. About four inches of this is enormously rich, as high as \$200 having been washed out of one pan of dirt, the balance of the ledge shows fine milling ore. The formation of the vein is porphyry and slate, coarse north and south. The lead is supposed to be an extension of the Good Hope, lying one mile south. The location of the Page ledge is such that it can be worked to a depth of several hundred feet by tunnel, which is a very great advantage. Mr. Baker was down from the mine on Tuesday and called at this office. He exhibited several pounds of ore taken from the ledge, that was literally alive with gold. These gentlemen have undoubtedly found a bonanza.

GOOD YIELD.—*Mt. Messenger:* Thirty-four thousand dollars was realized from the last two months' crushing at the Margaret Quartz Mine, and the probable yield this month, it is believed, will be twenty-two thousand dollars.

ONE hundred and eighty ounces a week is being taken out of the Ruby Gravel Mine. Last Monday, sixty thousand dollars' worth of very rich quartz was taken out of the Rainbow.

J. B. YORK cleaned up with his astral in his quartz ledge, this week, four hundred and fifty dollars, result of thirty-three days' run from fifty-three tons of ore.

DERBEC.—The Derbec gravel mine is coming to the front as a paying property. Since Sept. Denon took hold he has paid a debt of \$80,000, run 3,000 ft. of outside tunnel, and settled all the expenses of the mine working through a shaft. Those who have visited it say that this is the richest dirt mine they ever saw.

PHOENIX MINE.—The Phoenix Quartz Mine, at Sierra City, under the control of Mr. Deidesheimer, started up on Wednesday. The first work to be done is sinking a shaft. After a short time forty or fifty men will be put to work. A mill will also be built at no distant day. The Phoenix is a thoroughly prospected mine, and will give a good account of itself.

TUOLUMNE.
THREE SHIFTS.—*Tuolumne Independent:* Colby is going after the Divoll bonanza in good shape, and working three shifts. He calculates where the next gold-bearing strata makes into the vein—as indicated by the lay of the "country"—he will "get it" as big as ever. Anyhow, the "fat" of the "Big Nugget" claim will go in to haste the golden goose of the bonanza.

NEVADA.
Washoe District.

UTAH.—*Enterprise, May 12:* There will soon be active prospecting on the 2500 level, and the indications for finding ore are excellent.

CALIFORNIA.—The C. & C. winze, which is to go to the 2000 level, is progressing well, and the south drift, with which the winze will connect, is being pushed ahead as rapidly as possible. This will be a very important connection. From near this point will take place the reopening of the old ore bodies shut up at the time of the fire.

HALE & NORCROSS.—Although every one is confident that the recent find in the Hale & Norcross is but the top of a big body of ore, yet no one can say where the deposit may end. While most of those who have seen the deposit are loud in its praise there are those who say nothing is certain until shown up.

YELLOW JACKET.—Are extracting about 140 tons of ore per day, with an improved appearance in the mine. The prospecting sections are showing well. To the northwest is coming in a body of ore never before seen in the mine, and the existence of which had not heretofore been suspected.

CON. VIRGINIA.—On the 2500 level work has been discontinued in the face of the southeast drift, in order to allow the hot water to drain out at the face.

BEST & BELCHER.—The northeast drift on the 2500 level is cutting occasional streaks and bunches of quartz that give low assays. The ground is of a very favorable appearance.

UNION CON.—The winze at the end of the east

crosscut on the 2500 level is down some 20 ft. in a very favorable formation.

SILVER NEVADA.—The drift north on the 2500 level found a very favorable streak of ore, which, at that depth, is liable to develop into a good body.

CITIZEN.—The drift west cut some very rich ore, but, at the same time, the flow of water was such that it was not considered judicious to push forward, therefore the drift has been for a time discontinued.

NORTH GOLD & CRY.—During the week had some trouble with a four-foot streak of soft rock, but have timbered all up solid, and are now making excellent progress beyond the bad spot.

CROWN POINT.—The old upper levels still hold out well, and the usual amount of low-grade ore is being extracted and sent to the mill.

Columbus District.

NORTHERN BELLE.—*True Fissure, May 12:* The crosscut to the east from the end of the drift below the fifth shaft level, has been advanced 11 ft, its total length being 38 ft. The crosscut to the south from the level above, at a point 200 ft from the shaft, has been extended 18 ft, the total distance run to date being 54 ft. Its face continues to show streaks of black sulphurets, yielding assays as high as \$60 per ton. The slope at the eastern end of the ninth level has improved materially, and looks promising for the future. The daily output of ore has been about 54 tons. Both mills are running as usual and doing good work. Five of the stamps of mill No. 2 have been engaged a part of the week on ore from the Columbus Con. mine. A shipment of bullion amounting to \$13,941.52 was made on the 10th instant.

MOUNT DIABLO.—The intermediate drift below the third level, and west of winze No. 1, is giving a small amount of \$50 ore. The slope from winze No. 2 is yielding considerable \$95 ore from a two-foot ledge. A winze has been started on the ledge below this slope and is now showing eight inches of \$80 ore. The slope above west drift from Callison winze is looking well and turning out a good deal of ore. The ore is opening to the west as it is extended upward. The western part of the slope shows about two feet of \$75 ore, and the eastern end shows some 18 inches of \$65 ore. Two shipments of bullion were made during the week, one of \$5,681.06 on the 3d instant, and one of \$7,649.96 on the 7th instant.

Lewis District.

BULLION.—*Elko Free Press, May 1:* Four bars of Lewis bullion were received in Elko Tuesday afternoon. They were from the Betty O'Neal mine at that place, and came up on the freight train, consigned to the bank. This makes seven bars received from that mine during the past two weeks, and ought to be enough to pay off the miners and mill hands. The bullion was shipped to San Francisco Wednesday morning.

ARIZONA.

BULLION FROM WALKER.—*Prescott Courier, May 10:* Guilford Hathaway, the jolly giant, whose conveyance carries passengers from Prescott to the Howell reduction works, on Lynx creek, and vice versa, made the round trip yesterday and brought the best news of the season, which is that two of Hesser's six-mule teams started yesterday morning for the Atlantic and Pacific railroad, with between 12,000 and 15,000 lbs of silver bullion. Other teams, hauling the precious stuff, will start to-day, and similar shipments will follow. The company will pay its small army of workmen to-day.

CAVE CREEK.—*Arizona Gazette, May 10:* Mr. Dan White returned from Cave creek yesterday, and from him we glean the following items: Wm. Everson has struck a very rich streak of gold-bearing ore in his mine, and will have some worked soon. A clean-up from five tons of ore, worked in an arastra, from the McShackerty mine yielded \$60 in gold, or at the rate of \$12 per ton. The ore was taken from the entire width of the ledge, which is about 80 ft, without assorting, and the yield is satisfactory. The Golden Elcece mine, owned by Mr. Mack, is showing up well, and will prove a good piece of property. The Queen Sabie mine, owned by Messrs. Polhemus and Goodfellow, also shows well in free gold and permanency of ledge matter. Work on the Phoenix mine has been suspended for a time, the tools, furniture, etc., having been removed to the Golden Elcece.

COPPER.—*Mohave County Miner, May 6:* Until within the past few months but little attention has been paid to the numerous ledges of copper ore which abound in many parts of Mohave county, in fact so much has been written about our gold, silver and galena ledges that our copper deposits have been almost lost sight of. This has been owing principally to the fact that there have been no facilities for working copper ores in this county, and that the rates of freight have been too high to allow of their shipment elsewhere. The Atlantic & Pacific railroad, however, has changed all this, and mining men and prospectors are now turning their attention to our copper ledges as well as the other more valuable ones—more precious, but not less useful. Copper ledges abound more or less all over Mohave county, though little or no work has been done on any of them heretofore, except on Grand Gulch and Adams' claims, which lie in the extreme northwestern portion of the county, near the Utah line. The Grand Gulch M. Co. has erected large smelting works near the mine, which have been in successful operation for the past two or three years, but Mohave county has experienced little or no benefit from them, the mines and smelter being owned by citizens of Utah, and all of the bullion produced being shipped to Salt Lake. It is now proposed to move these works from their present location to the banks of the Colorado, at a point near Pierce's ferry where wood and water are abundant. The mines of Gold Basin and Lost Basin districts, on the opposite side of the river, furnishing the necessary fluxes in unlimited quantities. If this proposition is carried out it will be a great help to Mohave county, and more especially to the miners of Gold Basin and Lost Basin. In the southwestern portion of the county, on the western slope of the Wallapai range of mountains, are found some immense deposits of copper ore, of which we will endeavor to give a correct and exact description, though they should be seen to be properly estimated. The mines are situated near the western boundary of the Cedar Valley district, about 15 miles from Cedar and some 35 miles south of Kingman. The Atlantic & Pacific railroad passes within 14 miles of the largest of these claims. The copper mines of Mohave county are destined to take a prominent place among its many other rich mines,

and it will not be many months before old Mohave will be producing an output of copper bullion that will astonish everyone and make some of the copper companies in the southern portion of the Territory take a back seat.

WATER.—*Pinal Drill, May 10:* At the Queen Creek smelter, the tunnel from the bottom of the well has reached across the creek. An incline shaft will be sunk to reach the tunnel at the end thereof, which will intercept all the flow of water in the creek and give a plentiful supply for all purposes. This work will be finished within another week. They have struck water.

SILVER KING. Work at the Silver King consists in the sinking of the various shafts, with better results as they descend. In the Silver King mine itself they are sinking the working shaft deeper, and the ore is fully as rich as above.

COLORADO.

YORK GULCH.—*Register-Call, May 12:* A reporter of the *Register-Call*, yesterday, visited York Gulch and Vermillion mining districts. He found a large number of prospectors at work on different locations recently made. The most promising of these were the Barnacle and London, which have attracted a great deal of attention, and, through their discovery, have led to the discovery of other veins. Smock & Co. have a lease on the London, but, owing to heavy seepage of water, are not working below a depth of 40 ft. Development work is confined to drifting north and south. At the Barnacle, north of the London and on the same vein, a new pit has been started, in which, from the grass roots down to a depth of only two feet, mineral has been found. The water in the London is being kept under control by means of a "whip." In a conversation with Mr. Owens, the fact was elicited that the average of the ore sold from the Barnacle—ten tons—has netted an average of \$100 per ton; that the time devoted to its development—two men working—has paid them \$12 per day. A. E. Graham, Mark C. Christenson and Christian C. Johnson have made a location called the Denmark, southwest of the Barnacle. They have a pit down to a depth of 10 ft, and are tracing up the vein on the northeast, which they claim will cross or intersect the Barnacle. The service matter is decomposed, but as yet no mineral has been taken out.

KEYSTONE LODGE.—This promising true-fissure vein, situated in Quartz Valley mining district, is beginning to show up more splendidly than ever before. It is now opened up for a distance of over 400 ft in length. The main shaft is down to a depth of 110 ft, with a California whim, blacksmith shop and other surface improvements that are needed to continue deeper workings at that point along the line of the vein. East of the whim shaft is another shaft 80 ft deep. Both shafts are connected by a drift. A recent visit to the property convinces the reporter that an ore body—left in reserve—could be made to produce fully \$9,000. It is a characteristic of the vein that where it widens out the best pay is found—the mill dirt running six ounces gold per cord. The average of the ore, so far as the reporter has been able to obtain, has been four ounces gold per cord. The average width of the pay matter is fully four feet. The mill gold commands, at the banks of the city, \$15 per ounce.

IDAHO.

ANOTHER BONANZA.—*Ketchum Keystone, May 4:* Recent developments in the Junction prospect disclose a remarkable ore vein of 18 to 22 inches of solid galena and carbonates. The ledge is firm, uncovered 30 ft, and traced 800 ft. It is tapped by a tunnel starting but a few feet from the main road. The grade of ore is good, and the owners intend to put on a large force just as soon as the roads will admit of ore hauling. Want of space forbids further mention in this issue.

KETCHUM A SMELTING CENTER.—The Philadelphia Mining & Smelting Co. will immediately plant two additional smelters of 50 tons capacity each, to be constructed after the pattern of the famous Grant works at Denver. Contracts are made for all the necessary building materials, and the machinery is en route. The new plants will be finished and ready for operation within six weeks from date. They are to be placed about 100 ft from the original plants, and connected with the same by a shed. It is the purpose of this great enterprise to control the entire Wood River country and furnish a profitable market to the whole mineral region surrounding, in Idaho and adjoining Territories, and to be prepared at any time for the reduction of all smelting ores from any region, even at the necessity of new and additional plants. The said company will aim to concentrate their smelting facilities at this point, refusing no smelting ores and paying for the same the best possible cash price obtainable anywhere. Ketchum is destined to become, in the near future, a great smelting center. They will compete with the world, and, having plenty of capital and better facilities, will leave little room for the various one-horse stacks about the country. A capacity of 180 tons daily is certainly a test for the mineral wealth of Wood River. The adoption of Omaha prices, cash, less transportation, leaves no possible reason for a continuation of shipment, and the mines of Vienna, Sawtooth, Galena, Boulder, Lake creek, Ketchum, Warm Spring creek, Bullion and Bellevue will find their only profitable market at this place. As fast as the entire Wood River and surrounding country can turn out ore it can be sold for the highest cash price, and turned into bullion at the Philadelphia Co.'s works at Ketchum; and this settles the problem of finding a profitable market. Thus the only thing remaining is to extract the ore. The new smelting works will be fitted out in the latest and most approved style with every advantageous modern improvement, such as electric lights, etc.

THE GRANITE FORMATION.—*Wood River Times, May 10:* To the west of the limestone formation, on Deer creek, are located the Washington, Snowfly and Davitt mines upon one continuous vein, in a decomposed granite formation. The development work on the Davitt mine, so far, has opened up richer and larger bodies of ore as depth is obtained. The Star mine, which is a good property so far as explored, is in the same formation. The Parrell mine is another instance, located upon Deer creek. The majority of the developed properties are in white and blue lime.

THE NARROW GAUGES.—The Narrow Gauge mines are employing more men daily, and, with the Bannock, form a lively camp. A strike of fine ore in

the Narrow Gauge No. 1 was made last week and not reported. This location is in contact formation between granite and lime, and is regarded as a valuable property.

MONTANA.

MOUTON.—*Inter Mountain, May 9:* Everything is running smoothly at the Moulton, and the ore bodies continue to show no signs of exhaustion. On the 300 level the appearance of the south vein is very promising, and ten tons of high grade rock is extracted daily.

The working force of the Clear Grit has been reduced until the decision of the company with reference to the erection of a smelter to treat its product shall be made known. Mr. Kessler says that the mine in its present condition is fully capable of supplying a 50 ton smelter.

NEW MEXICO.

NIJES.—*Lake Valley Herald, May 10:* The Ore de Mesa, at the north end of the Magdalena, is raising free gold. Pat Leary has made a discovery of excellent mineral in the White mountains. It is reported that rich placer claims have been found in Los Cerrillos district, Santa Fe county. Peroxide of manganese in large bodies appears in the nameless mine at the head of Water canyon. The large ore dump of the Boston mine, at Pinal, is being carefully assorted preparatory to smelting. An important discovery of free flowing oil in Valencia county, by Albuquerque miners, has been confirmed. Rusty gold has made its appearance in the Cabinet mine of the Galinas, and by Prof. Simmon's assay yields a total value of \$666.75. An important strike of gold ore has been made 13 miles southeast of Santa Fe and four miles northwest of Gloria, as saying \$500 per ton. Col. Stapleton has discovered and located a body of excellent bituminous coal on Jaralosa creek. The coal lies in two veins, one five feet and the other two feet in width, divided by shale. Hardee & Hurlburt have sufficiently developed the Surprise mine, in the Bald mountain district to assure its sterling value. Last week ore taken from the bottom of the shaft assayed 692 ounces of silver, or \$788. This mine is in the same mineral belt in which all the recent rich properties were discovered. A large body of silver has been struck in the Silver King Mine, at Bullard's Peak. The character of the ore is similar to that of the Black Hawk mine, and reported equally as rich. The property is owned by Messrs. Bradley and Henderson, who have done a large amount of development work upon it. The strike was made at a depth of ninety feet. W. S. Ross, one of the old pioneers, has "hooked on" at last. Mr. Ross informs us that he has struck a vein of free gold bearing quartz, four and a half feet in width, at a depth of ten feet. It is no secret that the Jicarilla placer fields are as rich as any discovered. Where there are such immense deposits of gold in the gulches there must be some very rich leads. The Reserve, near Socorro, is worked by a well constructed double compartment shaft. No. 1 is down 230 feet; No. 2 has reached 125 feet, from the bottom of which a level runs west with a view of intersecting the main lead of the claim, and when that is reached it will be in solid formation. No stopping has yet been attempted. The dump of No. 2 displays a quantity of rich chloride ore.

UTAH.

BEAVER COUNTY MINES.—*Salt Lake Tribune, May 11:* Beaver county has a brilliant prospect of future greatness. The Horn Silver is sending out its steady stream of bullion, so is the Carbonate, Cave and some other mines, while the developments going on give promise of big things from several districts. From parties from Frisco we learn that there was a succession of strikes which have made but little noise, and yet are important events. The Piencho range, lying southwest of Milford, is about nine miles in length, and the greatest width three miles. On this range a few persons have been delving for the past 10 or 11 years, working under many disadvantages, and yet always with a hope that their day of prosperity would come with such abundance as to fully repay for all their toils and capital. Taking the range, and there have been strikes in the Magnolia, Creedmoor, Samaria, Mammoth, Talisman, Stalwart and several minor claims which lie with the trend of the range and extend nearly its entire length. The Samaria has several thousand tons of ore in sight, according to reports. The Talisman has 100-ounce ore in a 50-ft shaft, which struck the ledge 200 ft below the croppings on its dip. The Mammoth has a 700-ft tunnel with an equal amount of drifts, and has a large body of ore, lately struck. The strike is at a depth of 400 ft on the ledge, the ore being carbonate—50 or 60 ounces silver to the ton, and 55% lead. Cullen & Ryan, the owners, are preparing to ship extensively. The Stewart, owned by P. H. Martin and brother, is looking very fine, and has very rich ore. They are down about 200 ft and, with depth, the ore grows richer. This locality, known as the Star district, is all within from 5 to 15 miles of Milford, and hence is easy of access. In this connection it is well to give the products of Beaver county in the past, up to January 1, 1883: Horn Silver bullion, February 17, 1879, to January 1, 1883, \$6,938,698.73; Frisco M. & S. Co., January 1, 1881, to January 1, 1883, \$900,000; Shantice Smelter, 1873 to 1877, \$1,000,000; Troy, Riverside, Mountain Queen, etc., \$500,000; total, \$9,438,698.73. The Horn Silver has produced this year, to May 3d, \$1,210,600, and Frisco M. & S. Co. has been turning out a regular stream, so that the county has produced nearly or quite \$12,000,000 in precious metals. The Cactus property, near Frisco, is getting in shape with its concentrators to soon make itself known as a large producer, while other claims in that locality are being developed to good properties. The Cave mine sends out its steady stream of ore for reduction at the Frisco smelter, and in this district, lying east of Milford and extending over towards Beaver, there are being developed several good properties. The outlook of Beaver county is certainly bright.

REVIEW.—*Salt Lake Tribune, May 12:* The receipts of ore in this city for the week ending May 10th inclusive, were \$132,451.12, against \$173,724.51 the week previous, and \$118,371.82 the week before that. The shipments for the week ending May 5th, inclusive, were 68 cars bullion, 1,635,777 lbs; 5 cars copper matte, 148,410 lbs. Total, 73 cars—1,784,187 lbs. The Horn Silver shipments for the week were nineteen cars, \$57,000 of bullion; previously reported during the present year, \$1,210,500; present aggregate, \$1,267,500. The quarterly dividend, of \$300,000, which has been so regular under the present management, is officially announced for May 15.

Oregon Notes.

EDITORS PRESS:—While Portland to a person coming from San Francisco seems a dull and unimportant sort of place, it is, nevertheless, a very active and rapidly growing town, sharing largely in the generally prosperous condition of the State, business throughout Oregon having been unusually good the present year. This whole northwest country, Oregon, Washington Territory and British Columbia included, has, in fact, been well prospered of late, a condition of things due to a variety of causes. In the first place, the wheat crop of Oregon, its staple product, has been large, and is being disposed of at remunerative prices. The hop crop, too, both of this State and Washington Territory, has yielded abundantly, and was gathered in fine condition and found ready sale at prices more than double ever before realized by growers here. The lumber business, not only in Oregon and about Puget Sound, but even in some parts of British Columbia, has been lively and paid well. The mines, wherever worked, have produced a full average of bullion, while the great activity in railroad building has imparted additional life to all other industries, this last being the principal factor in bringing about so much improvement in the business of this entire northwest country.

Railroad Building and its Effects.

There are now approaching this region two trans-continental railroads, the Canada Pacific to terminate in British Columbia, and the Northern Pacific with branches terminating in Oregon and Washington Territory. Then, there is what is known as the Oregon Short Line, which, starting from Granger, a station on the Union Pacific road in Wyoming Territory, strikes northwest across Idaho, and, entering eastern Oregon, connects with the general railroad system of the State at Baker city. In addition to this, we have various local roads, some of them branches of the main overland lines, and upon all of which work is either now in progress, or will shortly be commenced. Among these local roads projected or being built, is one from this city to Astoria, also one leading east up the valley of the Columbia river, one from the coast up the valley of Rogue river, one leading into Grand Ronde valley. A narrow gauge track is being laid down to connect the town of Reno, on the Central Pacific, with southeastern Oregon, a part of this road being finished and in operation. The gap on the California & Oregon railroad is being closed.

When Oregon comes to be placed in direct railroad communication with the Atlantic seaboard it is expected that immigration will be greatly increased, the facilities for reaching the State from that quarter having heretofore been very imperfect. The prospect of this being accomplished so soon has already caused much government land to be taken up and considerably enhanced the value of both farming lands and town property in many parts of the State. In some farming districts the value of land has, through the building of railroads into or near them, been advanced from twenty to fifty per cent, the inhabitants being able now to dispose of their produce at a profit, which before they could not do, even wheat failing to bear cost of transportation to market. The railroads, employing so many men in their construction, have also created a local demand for the products of the farm as well as for fresh meats of all kinds, thereby affording the husbandman and stock-raiser a good home market, where before they had none or only a very insufficient one.

Every town along and adjacent to these new railroads is a very hive of industry, swarming with workmen, and teeming with busy life of every kind. East Portland is one great workshop, in which railroad machinery of many kinds is being turned out and thousands of freight cars being built in anticipation of the wants of the various companies.

As Compared With California.

Oregon seems to possess some advantages and some disadvantages, the natural features and conditions of the two countries being in many respects alike. Large sections of both are covered by rugged mountains, treeless sage lands and arid deserts. The mountains of Oregon are little worth except for their timber, they being for the most part well wooded. The sage lands, located mostly in the eastern and southeastern parts of the State, contain a great deal of bunch grass, affording a large amount of pasturage. The soil is generally good, and with irrigation produces fair crops of grain. The facilities found here for irrigation are, however, very limited, water being a rather scarce commodity. The deserts, occupying also the southeastern part of the State, except the little grazing afforded by their scanty growth of bunch grass, are nearly worthless. Southeastern Oregon and northwestern California are much alike, nearly the whole region being either hilly or mountainous, and well watered and timbered. The soil is everywhere good, but owing to the density of the forests in some places and the generally rough and broken surface of the country, it is not of much value for either farming or grazing purposes, though

there are some valleys and river bottoms where both these pursuits can be carried on to advantage, the whole district being well suited to fruit growing. On the California side of this belt much placer mining is being carried on, with a little also over the line in Oregon. About Coos Bay, a little north of the California line, extensive coal mines have been opened, and are now being worked.

Meteorological Conditions.

In the valleys and on the open uplands, which in both States, constitute the principal grain growing districts, the soil and climate are much alike, the most notable difference being that the climate of this State is more moist than that of California, the average annual rainfall here amounting to forty-six inches against only about half that quantity in San Francisco, where the rainfall fairly represents that of central California. Not only is the amount of precipitation here greater but it is distributed over a longer period than with you, we having only three, whereas, you have six nearly rainless months in the year. But little rain falls in California after the first of April and hardly enough to set the plows going before the middle of November. We usually have from two to three inches of rain in both April and May with nearly half as much in June and July, August being here the only absolutely or nearly dry month in the year. February is apt to be our wettest month and not December, as in California. In September we usually get from three to three and a half inches of rain with about the same quantity in October, followed by five to six inches in November, December and January, each. February almost always brings from twelve to fourteen inches and March about one half as much. Besides so much more rain, we have a greater number of cloudy days with more damp and misty weather generally than is experienced in

service than the Goodall & Perkins line have secured to these two cities. Against this company no word of complaint has ever been heard from either the commercial or traveling public, a fact that speaks volumes in their praise.

Portland, Oregon. H. D.

Pitch in.

We don't like to say anything reflecting even remotely on our old time miners—they are as good hearted a set of men as the sun ever shone on—but some of them are not sufficiently wide awake for their own interest. Here, in this country, are hundreds on hundreds of gold and mineral bearing quartz ledges, and nearly every old miner in the different districts knows of some one or more ledges from which a good prospect can be obtained, and probably most of them have made "locations," staked off claims, and did a little work on croppings. Now, if sufficient "elbow grease" had been laid out on these ledges to make a good showing in the way of development, and the ledges presented a favorable appearance, as many of them undoubtedly would do, there would be no difficulty in the owners either obtaining means to continue their work or selling their claims for fair prices.

The old timers have the best show at present, by reason of familiarity with the country, and should go for everything they can in the mineral line, and go for it with vim. There are "dead loads" of gold in our ledges and hills, and there are men and capital coming after it. Let the pioneers secure themselves, or place themselves in positions to have a share of the future golden era. Let every one who has not done so pitch in, secure a quartz claim or an interest in one, and go to work to reveal its merits.

Old timers are too liable to sit down in the

Situation and Surroundings of Portland

We give on this page a handsome engraving showing Portland, Oregon, and some of the notable features of the country surrounding it. The growth and prospects are themes which the Oregonian never tires to talk about, and they are matters in which all who enjoy the growth and development of the Pacific coast will take an interest. Of late years, Oregon and Washington Territory have secured a large share of the immigration to this coast, and the settlement of the country and the increase of its productions has been notable. It cannot be doubted that progress in this direction has but just set in, and that the coming completion of through lines of transportation eastward will add a new impetus to all industries and swell the population of all well placed towns, while at the same time it will plant new towns and new country homes upon the vast and rich region which is still unoccupied.

Portland—in latitude 45° 30' north, longitude 122° 27' 30" west—is a port of entry, the county seat of Multnomah county, and the commercial metropolis of Oregon. It is pleasantly located on the west bank of the Willamette river, about thirteen miles above the junction of the Columbia, and about 110 miles—by the river course—from the Pacific ocean. The city is located on a plateau, which gradually increases in height as it recedes from the river, until it forms a range of hills at the western extremity of the city, from which may be seen the snow-capped summits of Mounts Hood, St. Helena and Jefferson, the Cascade range of mountains, and the meanderings of the Columbia and Willamette rivers.

Approaching Portland on board a steamer from San Francisco, at the present time, one's first impression of the place is usually of a decidedly unfavorable character, owing to the line of dingy looking docks that obstruct the view. However, on landing and passing from street to street, a city of peculiar beauty is opened to the view, and one is surprised at the massiveness of the buildings and general thrift displayed in all branches of business. However, one blot on the otherwise unsoiled picture consists in the narrowness of the streets, most of which are but sixty feet in width. This defect, however, is soon lost sight of as we move from place to place and see on all sides unmistakable signs of wealth and comfort.

From the summit of the hills above referred to a scene of simple grandeur is unfolded. Away to the north the whole face of the country is dark with timber, through which the silvery water of the Willamette is plainly visible until it empties into the great Columbia, twelve miles distant. From far up the Columbia, the bright water may be seen as it moves steadily onward to the sea, and it is only lost to sight in the dim distance far to the west. Slightly east of north, and beyond the Columbia, the quiet little village of Vancouver is plainly visible, while, overlooking the river to the east of it, may be seen the Government reserve, with its barracks and parade ground, while in the latter a tall mast supports the stars and stripes as they proudly wave in the free air of heaven. To the right of this, and far off in the north, the pure white summit of St. Helena may be seen reaching above the surrounding mountains, standing 9,570 feet above the level of the sea; behind it, Rainier shows its cap of perpetual snow looming up in the heavens for 14,444 feet. Two other snow-capped mountains are seen to the right, but to grand old Hood, "the pride of Oregon," is ascribed the honor of capping the climax, as it sits in its silent glory, 11,255 feet high, off in the mountains to the east, perfectly formed, symmetrical and beautiful.

The people of New Mexico and Arizona are organizing to protect themselves against the Apaches. It is the fashion to growl at the military, but it appears that the Department forbids them crossing the Mexican line, or that of the San Carlos reservation in pursuit of hostiles. This gives the savage adequate protection. They maraud in Mexico until they are chased out, when they run for the reservation, killing, scalping, and burning on the way. Once across the line, their war parties are fed and recruited at Government expense until they are ready to go back to Mexico, when the same thing is repeated. An organization of frontiersmen will not observe the sanctity of San Carlos, but will cross the line and catch the Apache with his gun unloaded, and the difficulty will be solved.—*Exchange*.

MINING, to result successfully, admits of no neglect and must be watched attentively. Confidence and good staying qualities go far to make the successful mining man. Never give up while hope remains, for another foot further may bring the desired object. Never be carried away with the idea that heavy ore bodies must be the immediate result, or disappointment will follow. The cool, calculating, careful, energetic miner is the one who always wins. Good, honest mining ability, well encouraged, never yet injured a mine or harmed a district. About one dozen such men are needed in Aurora.—*Esmeralda Herald*.

PORTLAND, WILLAMETTE RIVER, AND MOUNT HOOD.

California, the excessive moisture of the climate having gained for the inhabitants of Oregon the absurd name of "Webteet."

The foregoing remarks apply only to Northern and Western Oregon, the annual rainfall here, as in California, increasing as we go north, and diminishing as we go south and east. Thus, it amounts at Roseburg, in the southern part of the State, to only thirty-six inches, while the quantity that falls at Olympia, seventy miles north of this place, amounts to sixty-three inches. Then, too, the country lying east of the Cascade mountains has a climate very unlike that of Western Oregon, the former having much less rain, but more snow, with colder winters, the climate being in most respects similar to that of Nevada, and other countries lying east of the Sierra Nevada. Eastern Oregon is an elevated, mountainous region, the various ranges being separated by fertile valleys or broad sage plains, the latter affording much good pasturage, but being, as a general thing, deficient in water and timber. In some of the mountains in this section of the State, gold mining, principally placer, is successfully and extensively carried on.

Notwithstanding its somewhat moist climate, Oregon is an exceedingly healthful State, quite as much so as California, which, of course, is saying a good deal in favor of her sanitary conditions. We have here very little rheumatism, consumption or other pulmonary complaints, while anything like endemic diseases is hardly known. Malarious fevers, so common in the Western States and along some of the river bottoms of California, occur here in but few localities, and always in very mild form. According to the mortality statistics of the U. S. Census, Oregon shows a lower death rate than any other State or Territory, save only Idaho.

What has tended to check the growth of Oregon, with her abundance of cheap land, fine climate and other natural advantages, has been her remoteness from the great supplying centers of population and her comparative isolation, she, having been until lately without a single railroad connecting her with countries outside her own borders. The steamships plying between this port and San Francisco have it is true, in good part made up for this deficiency, no communities having ever enjoyed a better

neighborhood of a good thing and never find it. New comers keep their eyes open and hunt for gold, and generally find it by industriously seeking it. George Klein went over to Deadwood, hunted for and found the continuation of the rich French Gulch leads, right where many other men had passed but failed to search; Shafter dropped on the famous claim above the Tower House, and is making a fortune; Banghart went up to Whiskytown and went to work and found the famous Mad Mule seam diggings and a fortune; Zent came from Oakland, and he and his partner went to work at Whiskytown and struck a \$2,000 pocket in less than no time; Lowry came up here after an absence of twenty odd years, and he and Brinard took their picks, shovels and pan, and after a few days persistent work struck the Middle Town pocket which shelled out \$10,000 or so, in a couple of weeks; Welsh and his partner got tired of not making much money at Redding and set to work at the head of Obey Creek and discovered a decomposed ledge from which they have taken more money than they ever expected to have when they started for California. And we might go on with this enumeration, but have said enough to remind all that we have the gold in our county, and that those who hunt for it are likely to find it.—*Shasta Courier*.

A LUCKY CAVE.—Last week a cave occurred at the mouth of Hamilton McCormick's tunnel, through which he was working a quartz ledge. There was so much debris he concluded it would be a great deal cheaper to hydraulic it, and prepared a sluice to wash the dirt, thinking he might get enough gold out of it to pay for the expense. When he cleaned up the gold he was surprised to find a very large number of nuggets varying in size from four bits to several dollars, and the nuggets alone yielded him about five hundred dollars, besides fine gold reaching over that amount. Mr. McCormick thought he might clean up a little gold, but had not the remotest idea of getting a thousand dollars from the debris. He says he had never seen any nuggets in the immediate vicinity of his place before, where he had been mining for many years.—*Transcript*.

THE ENGINEER.

The Canal Age.

Appropos of the movement at present in progress for the construction of the ship canal between Liverpool and Manchester, a writer in an ably-conducted North of England paper very pointedly draws attention to the probability of the remaining years of the nineteenth century being spoken of in history as "The Canal Age," his opinion being that the present indications are in the line of a large extension inland water carriage by means of canals, and that the problem of quick international communication has now been solved, almost to "finality," by steamships and railways. Whether or not finality has been reached by these two great civilizing agencies, it is undoubtedly the case that the prospects of canalization on a great scale for the immediate future bulk very largely in the eyes, both of commercial men and of engineers. Not only is there in hand the project of the Liverpool and Manchester Ship Canal, with its probable cost of \$30,000,000, estimated to make an income enough to pay the shareholders if only a single ship of 4,000 tons pass both ways every day, but there are also various other great inland waterway schemes, of national and international importance, either in hand or actually carried into execution.

The sum of \$200,000,000 has recently been voted by the French Parliament for inland canalization works, and it is thought that at least five times that sum will have been spent upon such works before the system of inland water carriage in France has been completed.

Many of our readers are familiar with the great engineering works which have resulted in the completion of a ship canal connecting the city of Amsterdam with the sea, and they scarcely require to be informed that it has proved to be a remarkable success, commercially and otherwise.

Additional canals are likewise in course of construction or projected in Belgium, a country well adapted by nature for such works.

Then, going into Prussia, we find that there is a prospect of a speedy beginning with the canal scheme which aims at connecting the Rhine, the Weser and the Elbe with the Baltic sea, at an estimated cost of upward of \$35,000,000. Proceeding further east, we should notice another proposal which bids fair to become an accomplished fact in the early future, which is a scheme to cut a ship canal to connect the river Danube with the Oder, and thereby joining the Black sea with the Baltic.

But in Russia it is proposed to enter upon even a much larger canal scheme, to wit: one to connect the river Dnieper with the Vistula, and thereby to bring the great ports of Odessa and Dantzic into direct communication.

A cable dispatch of May 10th says: A meeting of influential shipowners, to-day, in London, including representatives of 3,000,000 tons of Suez canal traffic, unanimously adopted a resolution favoring the construction of another canal across the isthmus, and appointed an executive committee to carry out the plans of the meeting. More or less similar schemes are likewise contemplated in other parts of the world—in Canada, Southern Europe, Southern Asia, the U. S., etc.

In our own country, the Florida canal may now be considered a definite fact. An organization was effected in Washington on the 9th instant, by the election of ex-Governor John C. Brown, of Tennessee, as President, with a large number of wealthy and influential corporators. Gov. Butler, of Massachusetts, among them. It was estimated that the canal will cost \$30,000,000, of which \$26,000,000 was reported as subscribed. The canal will be about 100 miles in length, and broad and deep enough for the largest class of ocean steamers. Its connection on the gulf side will be through the mouth of the Suwanee river, now so famous in song. It will connect with the St. John's river about twenty miles above its mouth.

WILL THE MISSISSIPPI CHANGE ITS MOUTH? The drawing off of a considerable volume of water from the Mississippi by the Atchafalaya river has created some alarm at New Orleans and neighboring towns on the great river. At the present time the Atchafalaya river is drawing away from the Mississippi a volume of water estimated at 300,000 cubic feet per second, or about one-fifth of the latter's entire volume, and is pouring it into the Gulf by a route only one-third as long as that pursued by the Mississippi, and having besides a much greater fall toward the sea level. The result of all this is that the Atchafalaya river is steadily increasing its volume to the detriment of the Mississippi; and if the outlet to the former is not stopped up, or prevented from increasing in size, New Orleans will, in time, be without a river, and all of the money expended upon the jetties will have been expended to no purpose. It is predicted by a prominent U. S. Engineer, that the Mississippi will cut its way into the Atchafalaya bayou, within a year or two, and make that the main channel from the mouth of the Red river to the Gulf. Should that occur, it would shorten the line to the Gulf about 200 miles, but as the cities along the present course and Capt. Eads will decidedly object to the change, it is likely that such steps as we suggested last season will be adopted to prevent the change, and at the same time allow of the overflow, in very high water from the Mississippi, through Atchafalaya bayou to the Gulf and thus save the country below the mouth of the Red river.

USEFUL INFORMATION.

Improved Leather for Pump Valves.

Almost every one who has had anything to do with leather valves, whether in connection with blowing engines or other machinery, says the *Iron Age* knows the difficulties attendant upon the use of ordinary leather for the purpose. Various substitutes for leather have been tried, among which may be mentioned rubber in various shapes, but serious objections to all have been evident, even on slight trial, and the demand for a really good article for this purpose is widespread. The Shultz Belting Co., of St. Louis, recently introduced a peculiarly prepared article of leather for this use, which, says the *Age*, by its characteristics possesses many advantages for such uses. In positions where ordinary leather has in a few days broken off by the hinge-like motion to which valves are subjected, valves made of fulled leather have proven very durable. A peculiarity is that the material thus produced becomes softer the more it is bent and worked. The Cambria Iron Co., placed valves made of this material in the most severe parts of their engine, and up to a very short time since they were still in use and were working satisfactorily. The statement is made by the general manager of the company that valves made of ordinary leather in the same position only last a few days. From the fact that valves made of this material, whenever introduced, have given very great satisfaction, it would seem that the employment of leather of this kind, for the purpose, was a matter in which iron manufacturers generally are interested.

RELATIVE COSTS OF STREET LIGHTING BY ELECTRICITY AND GAS IN NEW YORK.—New contracts for lighting the streets of the great city of New York have just been awarded, to begin May 1st. The price to be paid for gas lighting for the closely inhabited part of the city, in which by far the larger portion of the lamps are located, is \$17.50 per year per light. In the outskirts and sparsely inhabited regions, from \$19.50 to \$32.00 per gas light is to be paid. The use of electric lights will be continued in portions of Broadway, Fifth Ave., including certain parks and squares, in all, a length of about six miles, at seventy cents per night per light. Arc lights are used of the Brush Company, also of the United States Company's styles. Each electric light displaces six gas lights. The contract price for each electric light amounts to \$225 per year per light, which is rather more than double the cost of gas in the chief parts of the city. It is conceded, however, that the quantity of light furnished by an electric light is much greater and better than that yielded by the six displaced and dingy gas lamps. The streets that are illuminated by the electric lamp present an attractive and brilliant appearance. Reckoned by quantity of light supplied, the arc lamps are far cheaper than gas. Not so, however, with the incandescent system—the Edison system, for example, which is not at present used for street lighting in New York. Each small Edison light, not quite equal in force to an ordinary gas light, costs rather more than gas.

PREPARING FOR ACCIDENTS.—The passenger engineers on the New York, Lake Erie and Western Railroad are being furnished with a small box of appliances to be used in case of accidents. They are requested to carefully read the instructions which accompany the box, in reference to the proper treatment of injured persons, to have their firemen do the same, and to keep the box constantly on the engine, where it can be obtained at a moment's warning. The box contains broad and narrow bandages, with safety-pins to fasten them, a compress of dressing cotton covered with cotton gauze, hemostatic cotton to stop bleeding, surgeons' plaster for use in bruised wounds to draw parts together and permit healing by first intentions, a bottle of soothing ointment for cuts, burns, scalds, etc., and a bottle of tincture of arnica. The little pamphlet which accompanies the box gives minute descriptions how to bandage any part of the body, and illustrates the same by a number of cuts.

A COLONIAL EXHIBIT.—A prominent and interesting feature in the approaching Amsterdam Exhibition will be the Colonial Section, in which will be shown specimens of the production and resources of the entire colonial world. It will comprise examples of everything interesting in the natural history of the different colonies. A second category will comprehend a complete collection of objects illustrative of the civilization of the tribes and people indigenous to the several colonies, their manners, customs, domestic economy, arms, dress, etc. A third group will consist of everything of use or interest in colonial enterprise—the appliances of travel or exploration, the military equipments, manufactures, coinage, etc., of the European settlers.

BRASS WORK that is so dirty by smoke and heat as not to be cleaned with oxalic acid should be thoroughly washed or scrubbed with soda, or potash water, or lye. Then dip in a mixture of equal parts of nitric acid, sulphuric acid, and water; or, if it cannot be conveniently dipped, make a swab of a small piece of woolen cloth upon the end of a stick and rub the solution over the dirty or smoky parts; leave the acid on for a minute and then wash clean and polish.

CAUSE OF DARKENING IN BRONZE WORK.—The Society of Architects, of Berlin, have been investigating the subject of the change of some kinds of bronze to a black hue. It appears that one of the most notable statues in that city had become covered with a darkish layer, while an old cannon before the arsenal had retained its fine green color, the two having been exposed to the same atmospheric action. Upon being analyzed, the bronze of the cannon was found to consist of nine parts copper and one part tin; the bronze of the statue, however, exhibited a good percentage of zinc, and to zinc the change of color is regarded as due. In order to ascertain the facts in the case definitely, several copper alloys were subjected to the action of a copper solution. The result was that the alloys of tin and copper alone took the green color, while the alloys containing zinc became more or less black, according to the quantity of zinc they contained.

A SO-CALLED "ELECTRIC FLANNEL" has been invented in France by Dr. Claudat, who affirms that it is efficacious against rheumatism. This flannel contains, per kilogram of wool, 115 grams of oxides of tin, copper, zinc, and iron. A series of threads of the tissue saturated with these metallic products are woven alternately with the ordinary threads. The flannel so prepared forms a dry pile. M. Drincourt, professor of physics at the Rheims Lyceum, and M. Portevin, of the polytechnic school, have proved, independently, by very precise experiments, that Dr. Claudat's flannel liberates electricity, either by simple contact, or better, in contact with the products of transpiration when the tissue is applied to the body.

HEMLOCK BARK EXTRACT.—There are produced annually in North America 100,000 barrels of hemlock bark extract, of which a single Boston firm produces 72,000 barrels. They own nine extract works, and operate 23 tanneries. All the tanneries of the United States consume annually 1,250,000 cords of hemlock bark, produced in nine States. As the yield of bark is about seven cords to the acre of hemlock timber, the yearly consumption implies the clearing of 178,000 acres.

A RIVAL FOR KRUPP.—Judging from recent accounts, there is now growing up on the banks of the river Tyne, in England, an establishment which, it is stated, promises to bear comparison with Krupp's enormous works at Essen, Germany, in addition to a shipbuilding yard capable of turning out vessels of war of the largest size.

GOOD HEALTH.

Constipation.

Constipation is the beginning of many diseases. It is the most prevalent of all affections among those not accustomed to out-door activities. It frequently commences in infancy through the neglect or ignorance of parents; and the health sometimes becomes permanently impaired, before the cause is discovered by the physician.

There should be at least one free and natural movement of the bowels every day, and when that is not the case, all proper means should be promptly employed to bring it about. Nature intends that the waste material, after digestion is completed, shall be passed out of the system within a certain time, but if that time is exceeded it commences to be absorbed, thus the blood is poisoned and the vital force is impaired; hence the body becomes an easy prey to disease.

Dyspepsia is generally the first diseased condition caused by constipation. The liver soon becomes involved as a result of indigestion, then the kidneys. It is evident that a long continued derangement of either of these important organs must result most unfortunately. All experience proves that habitual constipation is a very unsafe condition of the system, and one liable at any time to develop incurable diseases.

Various plans have been devised for the cure of this distressing complaint; but we do not believe in restricting the treatment to any one remedy. To secure success, various methods must be employed, and employed persistently. Some will after a while lose their effect, and others must be substituted; no quarter should be shown until this great enemy to health is overcome. The habit of taking purgative medicines to relieve the bowels often increases the trouble; that is, the system becomes accustomed to this remedy and there is no relief without it; the remedy debilitates, and it becomes only a question of time how long the treatment can be borne.

As in these cases there is always a torpid liver, we should commence the treatment with a mild cathartic—as two or three liver pills; and then pay especial attention to the diet. Bread made from crushed wheat or oat meal should be used; we should not restrict the patient as to other foods, except as to quantity. He should eat enough, but not overload the stomach. A tumbler of cold water with a teaspoonful of table salt dissolved in it and drank every morning half an hour before breakfast, often acts like magic in restoring the bowels to their natural condition. There are many cases of obstinate constipation, where the whole trouble exists in the lower part of the rectum, by impacting of fecal matter, due to feeble action of the muscles, and to a congested and dry condition of the mucous membrane at that point.

Regular and vigorous out-door exercise is all

important. Kneading the bowels with the hands has been recommended; also, the drinking of water frequently, to which we should always add a little table salt.

The frequent use of a syringe should be avoided, for much the same reason that cathartics ought to be avoided. No harsh or very active treatment is required in these cases; but mild remedies may be employed persistently; in fact, they should never be resorted to until the bowels become regular and the health is restored. We believe that a majority of cases are curable. We know of one case of great severity that lasted twenty-two years, and was then cured, although the general health has never been fully restored. *Hall's Journal of Health*.

THE HYGIENE OF SHOES.—That the shoes we wear are seldom made of the proper shape has been often pointed out by scientific writers; but the habit and fashion are not easily changed. The poor suffer more from this cause than the well-to-do; for cheap shoes are generally worse in pattern than more costly ones, and being clumsier and more flexible, cause greater distortion to the feet. Deformities of the feet and toes are especially frequent among the poor. This matter was the subject of an able and interesting paper, read by Col. Ziegler, Chief Surgeon of the Swiss army, at the Geneva Hygienic Congress. He stated that every year 800 recruits are rejected for malformation of the feet, resulting from badly-fitting shoes. The foot is in reality a bow, so elastic that at every step it contracts and expands, lengthens and shortens, and a line drawn through the center of the great toe intersects the heel. Shoe-makers do not give room enough for the lateral extension of the great toe, confining it until it is forced against the other toes, giving rise to inflammation, corns, ulcerations, and sometimes true articular inflammations. Another evil is flat-footedness, whereby the arch of the foot is converted into a straight line, and prolonged walking rendered impossible. Another cause of this defect is the carrying of heavy weights at an early age, but in most cases perfect shoes would restore the foot to its normal condition. A test of a perfect pair of shoes is that, when placed together, they should touch only at the toes and heels; the soles should follow the sinuosities of the feet, and, to give room for their expansion, should exceed them in length by fifteen or twenty millimeters. *Popular Science News*.

THE INCREASE OF INSANITY in the past few years, as shown by recent publications of the Census Bureau, appears to be very great. According to this statement the number of insane persons per thousand population in the United States has doubled in the past ten years. This statement is probably somewhat in excess of the real facts, as the inquiries in the last census were much more searching than on former occasions, but at best it seems that the percentage of insane persons in the population of this country must have increased very materially. It is a startling fact that out of our 50,000,000 of people, over one half million, or one per cent. of the population, are either insane, idiots, deaf mutes or blind, are suffering imprisonment for crimes committed, or are inmates of reformatories or poor houses.

SMOKING FOR HEALTH.—"Don't you know it's very wrong to smoke, my boy?" said an elderly looking lady in a railway waiting-room, to Young America, who persisted in puffing a cigarette, much to the old lady's discomfort.

"Oh, I smoke for my health," answered the boy, emitting a volume of smoke from his mouth, which almost strangled the old lady.

"But you never heard of a cure from smoking," continued the old lady when she had regained consciousness.

"Oh, yes, I did," persisted the boy, as he formed his mouth into a young Vesuvius; "that's the way they cure pigs."

"Smoke on, then," quickly replied the old lady; "there's some hope for you yet!"

THE *Lancet* says: "It is high time that attention was directed to the subject of narcotics generally, and the use of chloral and bromide of potassium in particular. Incalculable injury is being done, and public opinion is being grievously misled by the tolerance given to the use of 'sleeping drafts,' falsely so-called. In regard to this matter and that of the reckless use of hypodermic injections of morphia, the profession should seek to form a deliberate judgment, and gravely deliver itself. At the present moment we are under a heavy responsibility, which it is idle to deny and vain to disown."

WARM water, of all remedies, is the one of most general application. Cotton dipped in warm water makes the best and cleanest poultice that can be used. It is the most healing application for cuts, bruises, wounds, sores, felons and other inflammations. A very convenient way in case of felon or other painful abscess, is to hold the hand for hours in water as warm as can be comfortably borne. *Journal of Health*.

THE possibilities of electricity in medicine, according to a popular German physician and medical writer, seems to be almost without limit. The writer referred to, Dr. Suprunenko, reports quite a number of cases which have hitherto never been treated with electricity, but which in his recent practice have yielded to a moderately strong induction current.

St. Augustine College—J. H. D. Wingfield, Benicia, Cal.
The Home Seminary—Miss M. S. Castleman, San Jose.
Assessment Notice—Santon Gold Mining Co., S. F.
Meeting Notice—Gagnere Mining Company, S. F.

Passing Events.

The late rains have been good for farmer and
miner as well, and the water that has fallen is
being utilized, as far as possible. We note
elsewhere new tactics on the debris case by
which the attorney of mining companies is
served with injunction papers in default of the
proper officers being served.

From all points we hear of men going to work
for copper, and copper prospects are being de-
veloped rapidly everywhere. The experience
of a few mines has encouraged miners to look
for this metal, and it is gradually becoming
more important every year in the cost of pro-
ducts of this coast.

New smelters are being put up at Ketchum,
Idaho, and that point expects to be a smelting
center before long.

Work on the new borax deposits in San Ber-
nardino county is being prosecuted, and it seems
likely that a large borax field will be developed.

In Sierra county, several rich strikes are
noted, and a general revival of the quartz in-
dustry of Nevada county is going on. Men are
prospecting, and many new mines are being
opened. In Utah, the mining prospects are
very encouraging. From Lower California
comes news of new placer mines, but it is no
doubt in a dry region.

Arbitration in Mining Matters.

At the organization of a mining district in
Arizona the other day, a "committee of protec-
tion" was organized, to consist of eleven mem-
bers, whose duty it is to arbitrate any dispute
which may arise in the camp.

Now, this seems an exceedingly sensible
thing to do. Probably the miners themselves
are just as good judges of what is right and
proper as two or three courts and a dozen or
two lawyers. They may not be up to the law,
but are more apt to dispense justice, and dis-
pense with law. Most of the disputes in mining
camps—aside from brawls—are on questions
connected with location and claim, and on
these subjects the miners are as well posted as
anyone. In settling questions of this kind by
arbitration, much valuable time is always saved,
as well as money.

We have a great deal too much law in all
walks of life, and there is by no means so much
confidence in the justice of legal decisions as
there was formerly, since the justice is so often
entirely lost sight of in the web of legal techni-
cality. It really seems as if justice could be
more properly administered without the for-
malities and technicalities, when experience has
so frequently shown us what stumbling blocks
they are. Still people seem to cling to the old
traditions, and while blaming the legal fraternity
for its adherence to the "precedent," look with
shyness at anything for which precedent is
not shown. But awards by arbitration are re-
cognized by law and the practice is one very
ancient.

In such isolated localities as mining camps, or
farming communities, in new States and Terri-
tories, it seems as if award by arbitration would
work well. The system possesses the merit of
simplicity. When a dispute arises between
neighbors, involving property, where no
agreement can be satisfactorily made by the
parties themselves, other neighbors acting as
arbitrators are apt to come to a correct decision,
as if a whole court full of lawyers was em-
ployed. And what is important, in a new com-
munity, no money need be spent, or time
wasted. It has been found that in criminal
matters in mining camps the decisions of the
citizens, carried out promptly as they are some-
times, generally cure the evils they are intended
to remedy, perhaps as well as more formal pro-
ceedings.

It is not, by any means, intended to imply
that such a "committee of protection" should
usurp all the functions of the courts, but by its
help much needless litigation could be pre-
vented. Many mining camps have been kept
back for years by litigation which kept pend-
ing for months and months, when a vigorous
searching out of the truth, and prompt deci-
sion, would have been to the benefit, not only to
the litigants, but the whole community, for
the community suffers in these contests by the
cloud the litigation throws over the camp. The
Arizona miners have well named their committee,
therefore, for they can protect the people from
the evil effects of the quarrels of a few.

SAVING GOLD.—At the Indian valley mine,
Plumas county, every precaution is taken to
save the gold, which is very fine and difficult
to catch; an unusual proportion of silvered
plates is used, then there is a revolving cylin-
der, into which the sand from the batteries is
put and thoroughly worked to secure what
amalgam it may contain; after being worked in
this cylinder the sand is conveyed to an oscil-
lating pan where it is again shaken and ground
by pieces of iron and round balls weighing four
or five pounds. In the sluices that carry away
the tailings, boxes are placed that serve as traps
for catching any gold or amalgam that might
have escaped; these are examined every few
days, in order, not only that the gold may be
recovered, but also that the fact of its escaping
from the mill may be known, and the cause as-
certained and remedied.

BIG BEND TUNNEL.—In an item published
last week concerning the rapid work done in
the Big Bend tunnel, Butte county, in the mat-
ter of drilling, it was inadvertently stated that
the drills used were Ingersoll's, whereas the
whole drilling outfit in the tunnel is a Burleigh.

The President has appointed Norman H.
Camp, Superintendent of the Assay Office, I. T.,
vice William Walters, suspended.

PROFESSOR KOST proposes to make a geological
survey of Florida at his own expense.

Cupellation Loss in Silver Assay.

The term "cupellation loss" is applied to indi-
cate a minute loss of silver unavoidably sus-
tained in the process of cupellation in assaying,
which arises from a small portion of that metal
being mechanically carried along with the lith-
arge into the body of the cupel. The amount
of this loss increases with the quantity of lead
present in the assay (whether contained origi-
nally in the assay or added subsequently for the
purpose of slagging off the copper, etc.); it is
relatively greater, as the silver globule is larger,
but represents a larger percentage of the silver
actually contained in the assay, in proportion
as the silver globule obtained diminishes in size.
It has, however, been experimentally proved
that in assays of like richness in silver, this
loss remains constant, when the same tempera-
ture has been employed and similar weights of
lead been oxidized in the operation.

In the blowpipe assay this loss is not con-
fined to the ultimate operation of cupellation,
but occurs, though in a less degree, in the con-
centration of the silver lead, and in the pre-
vious scorification of the assay, had such opera-
tion preceded the concentration. The total
loss in the blowpipe assay is found, however,
to be less than in the ordinary muffle assay,
since in the latter case the whole of the oxid-
ized lead is directly absorbed by the cupel.

In mercantile assays of ore it is not custom-
ary to pay much attention to the cupellation
loss, and the results are usually stated in the
weight of silver actually obtained. Where,
however, great accuracy is required, especially
when the substances are very rich in silver, the
cupellation loss is added to the weight of the
silver globule obtained, in order to arrive at a
true percentage. The proper amount to be
added for this purpose in blowpipe work is
shown in the annexed table, which is slightly
modified by George Attwood from Plattner's:

Actual per cent- age of silver found by assay.	Cupellation Loss, or Percentage of Silver to be added to the actual percentage found by assay in order to show the true percentage of silver contained in same, the entire amount of lead in or added to the assay being the following multiples of the original weight of assay.

Lower California Mines.

The peninsula of Lower California no doubt
has many places where gold exists, which have
not yet been found, but the region is such a
barren and dry one that there is little encourage-
ment for prospectors. Even if they do find
gold, if it is not on very rich ground it will not
pay to work, owing to scarcity of water. There
have been mines worked there on a small scale,
in different localities, but Americans have made
very little money in the country. Every now
and then, however, we hear of new mines being
discovered, and news of one of those discovered
reached here this week. A dispatch from
Guaymas says: By the arrival of the schooner
Rambler, twenty hours from Moleje, the news
of the placer discovery in Lower California
is confirmed. Manuel Grejalba came over di-
rect from the mines and brings some six pounds
of coarse gold, among which is a gold nugget
weighing sixteen ounces. The major part of the
gold resembles that found at Mormon Gulch in
California. Being interviewed, Mr. Grejalba
said that the mines, so far as prospected, were
about five miles wide by about twenty in length,
and situated in a valley of the mountains some
two hundred miles from Moleje. There were
only a few natives at the mines when he left,
but quite a crowd on their way there. Mr.
Grejalba has found a gold quartz mine near the
seat of the placers, and only came over to get
supplies and tools for the working of his claim.
The mines are only some fourteen miles inland
from the Angel Gardia bay, opposite to Buron
island, where there is a good harbor, plenty of
water, wood, etc. A large party starts from
here on the Rambler, which leaves on Friday
and takes all she can carry. Mr. Garcia also
came over in the Rambler, and brings about
seven pounds of coarse gold. The town of
Guaymas is alive with miners anxious to reach
the other side. Another schooner has been laid
on, and will sail by the end of the week.

Working in Foul Air Underground.

It is one of the characteristics of miners that,
at every mining accident, even in fiery
collieries, there is a desire on the part
of the men employed, to enter the mine to
rescue their fellow workmen. There never
was an accident on this coast that there was
lack of volunteers to help imprisoned miners,
and upon the Comstock, particularly, many
instances of heroism and bravery may be re-
called. In England, where frequent accidents
occur in the coal mines, there are always plenty
of men to go into the dangerous galleries, and
a commission appointed to enquire into the
cause of mine accidents recognize this fact so
well that they now propose to instruct men in
the proper means of working in foul air, under-
ground, and having the necessary appliances
ready for use at any time.

In fact, the English Government has taken
hold of the matter and the Home office has
issued a circular to the mine owners, asking
them to take an active interest in promoting
arrangements, which may contribute towards
the general introduction of efficient means for
saving life. After proper examination, the
Secretary of State recommends the use of the
Flensburg apparatus, by which men may remain
in localities where the atmosphere is in a highly
vitiated or irrespirable condition. Practical
and conclusive proofs are cited of the readi-
ness and efficiency with which the Flensburg
apparatus can be applied to the saving
of life after explosions; and illustrations
unfortunately occur quite often that show
the necessity of having some such thing
ready for immediate use. It is suggested that
the system upon which lifeboat stations have
been organized and developed with such bene-
ficial results might be applied without difficulty
to the creation, in mining districts, of stations,
where the Flensburg apparatus should be stored in
sufficient numbers, and maintained in readiness
for immediate use, and where the instruction
of men from the surrounding coal mines in its
use, should be systematically carried out. A
rescuing party could thus be speedily on the
spot after the occurrence of an accident in a
particular district, in which a station had been
established. It is necessary, however, that the
men shall have some experience with the ap-
paratus and the commission suggests that cer-
tain collieries in each district should be supplied
with six sets of apparatus and lamps, together
with the necessary appliances for making and
compressing the gas required. At each of these
collieries, which should be in such a position
that a special train could be obtained and dis-
patched at the shortest notice a dozen or more
of the men who work there should be trained to
use the apparatus and lamp. Facilities are
also to be given to men working at other col-
lieries for learning how to use the lamps.

The apparatus to which we refer is thus de-
scribed in the Reports of Her Majesty's Inspec-
tors of Mines:

"The apparatus, which is carried upon
the back of the diver, miner or explorer, con-
sists of a strong sheet copper cylinder, twelve
inches by six and a half inches, with domed
ends, and capable of holding four cubic feet of
oxygen gas at a pressure of sixteen atmospheres.
Above the cylinder and attached to the side of
it, is a square metal box, twelve inches by
twelve inches by four inches, to contain the
carbonic acid filter, which is a box of vulcanite,
divided into four compartments, and with a
wooden lid made airtight by an india-rubber
washer, and having an inlet and an outlet tube;
this box is filled with a packing of ordinary tow,
interspersed with two pounds of stick caustic
soda; the exhaled breath passes twice up and
down through the interstices of the tow, by
which it is finely divided, and thoroughly freed
of carbonic acid by the caustic soda, the excess
of moisture collecting under a perforated false
bottom arranged for the purpose. A flat bag
of vulcanized india-rubber is fastened to the ap-
paratus, and is connected by an india-rubber
pipe over the shoulder to the outlet pipe of the
filter; the bag is also in communication with
the oxygen chamber, and the supply of oxygen
to the bag can be regulated by a jam screw
valve under the control of the wearer.

"An india-rubber mask is made to fit tight
to the face, and is held in place by straps buck-
led up at the back of the head; the mask is fitted
with a pair of flexible valved pipes, the one for
exhaling being in communication with the inlet
pipe of the filter, and the other for inhaling in
communication with the air bag. The exhaled
breath having passed through the filter enters
the bag in a purified state, and then meeting
with its complement of oxygen is fit to be again
inhaled. The bag being perfectly flexible, readi-
ly expands or contracts as the breath passes in
or out of it, so that no effort is required in res-
piration. Foster and Fleuss's patent safety

mining lamp is a modification of the limelight, methylated spirits of wine being used instead of hydrogen gas, and consists of a strong copper sphere, seven inches in diameter, and capable of being charged with oxygen at a pressure of from sixteen to twenty atmospheres. To the top of the sphere is attached a small spirit lamp, with two wicks, between which through a small jet a minute stream of oxygen regulated by an adjusting valve on the sphere, is allowed to pass, carrying the flame against a cylinder of lime held on a stand placed to receive it. "The light is covered in by a double dome-shaped metal casing, having an annular space left between its inner and outer surfaces which is filled with water; discs of plain glass are inserted opposite each other in the inner and outer casings, and a small outlet valve is fixed in the inner case near its lower part for the escape of the products of combustion, from the inside of the casing into the annular space filled with water between the two cases, through which the gases bubble and escape through another outlet valve fixed on the top of the outer case. The cover is attached to the lower part by means of a screw, an air-tight joint being made by a leather washer seating."

The inventors state that the lamp "will burn for four hours equally well under water, in carbonic acid, or in firedamp;" and that "it cannot get hotter than boiling water."

English Investments in the Pacific Coast Mines No. 4.

[Prepared for the MINING AND SCIENTIFIC PRESS by H. DEGRAD.]

The Last Chance S. M. Co. (Limited.)

The mines of this company are situated at the head of Bingham canyon, Oquirrh mountains, Utah. Though but little developed when purchased by the English company in 1872, the Last Chance lode showed in its upper workings a body of high-grade gold and silver-bearing ore. The company organized in London, with a capital of £100,000—20,000 paid up shares, £5 each. The company, having accepted the property on the favorable report of their own examiners, proceeded to open up the mine in a systematic and thorough manner, erecting at the same time suitable works for the reduction of the ore, considerable quantities of which were disposed of at a good price before these works were got in readiness. During the first year of the company's existence, there were disbursed to the shareholders seven dividends of two shillings each—fourteen shillings in all, the last dividend having been paid in July, 1873. While the ore in the upper portions of the mine carried so much lead that it could not well be milled, there was still not enough to fit it for treatment by smelting. To supply this deficiency, the company bought the Hooper lode, lying contiguous, the ore from which, though poor in the precious metals, being high in lead, was mixed with that from the Last Chance mine, the two turning out a considerable amount of fair-grade smelting ore. For a couple of years the company was tolerably prosperous, when, the line of permanent water in the Last Chance mine having been reached at a depth of about 400 feet on the vein, the ore changed from oxidized to sulphuret, rendering it so intractable that it could neither be smelted nor disposed of on the market. In this dilemma the company, instead of providing concentrators, or putting up suitable reduction works, as they should have done, suspended operations, there being at the time some debts outstanding against them. These debts remaining unsatisfied and others accruing, no net earnings having meantime been made, the property was attached and sold, after which the company in London went into liquidation and their affairs were finally wound up. This done, a new company, called the Last Chance Consolidated, was formed, the most of the shares in which were taken by the members of the old company. The property was redeemed, but the new concern being delayed clearing away the financial wreck and settling other preliminary matters, did not get into the field and fairly at work until the fall of 1880, since which time the company have been engaged in further developing their mines and putting them in shape for future production, no net earnings during the interim having been made.

Although the new company is believed to have a valuable property, they have not as yet put up any additional reduction works, it being their policy to avoid further expenditures until their mines have been so fully proven that they will run no hazard in incurring such expenditures to a reasonable extent. They have it in contemplation to drive a tunnel that while it drains the Last Chance mine will serve as an adit for the removal of the Hooper ores, the erection of concentration works also entering into their future plans. There have been opened up between fifteen and twenty thousand tons of ore in the Hooper mine. This ore is poor in silver, averaging only about twelve ounces to the ton, but rich in lead, carrying from thirty to forty per cent of that metal. Under the new administration both mines have been worked on tribute, the miners receiving about seventy per cent of the ore extracted and the company the balance, the latter taking and selling the whole of the ore and dividing the proceeds in the above proportions.

Pursuing this policy the company realized enough profit to defray current expenses, effecting the thorough exploration of their mines at the same time. The ore in the lower workings of the Last Chance mine, now filled with water, though base, was rich in gold and silver at the time operations were suspended there. No attempts will be made to unwater this mine till the projected tunnel shall reach the lode. Parties conversant with the situation are of the opinion that the prosperity that marked the early history of this property will, under the

superintendent, having heard big stories of gold mines in South America, suddenly made a break for that country; the foreman, for these or other reasons, having also lit out for parts unknown. The general manager, who resided at Salt Lake City, instead of stopping as he should have done at the mines, sent up another superintendent to fill the places so unceremoniously vacated, offering the new incumbent a handsome bonus on condition that a certain quantity of ore were gotten out in a specified time. The result was that a good deal of lime

FIG. 1.—AUSTRIAN SYSTEM OF TIMBERING IN OPENING TUNNELS.

present judicious management, be eventually restored to it.

The Davenport and Matilda Mines.

Located in the Little Cottonwood canyon, were sold to an English company in 1872. Prior to the sale the Davenport lode had been somewhat developed, a little exploratory work having also been done on the other lode. Four or five hundred tons of ore, carrying about twenty per cent lead and fifty ounces of silver to the ton, had up to that time been extracted and shipped or smelted. The new owners, on their coming into possession of the property, erected two

rock was sent to the surface and made to do duty for ore. And so, between incompetence, dishonesty and extravagance, matters went from bad to worse, and the company getting heavily in arrears to their workmen and others, their property was attached and finally sold to satisfy the claims of their numerous creditors. Passing into other hands these mines have since been worked with moderately good results, though their upper levels are now about exhausted; and if production is to be kept up, further exploratory work will have to be done, to which end new and costly hoisting and pump-

FIG. 2.—BOTTOM HEADING FOR TUNNEL.

furnaces, with a joint capacity of fifty tons per day. Large and commodious buildings, with very complete machinery, were put up near the mouth of the canyon, the motive power being water obtained from Cottonwood creek. Numerous buildings, with hoisting works, were erected at the mines, a substantial tramway having also been laid down for facilitating the transportation of the ores from the mines down to Grizzly Flat, at the head of the canyon, where they could be loaded on wagons. A steam saw mill was brought in and quite a town built up at Grizzly Flat, situated a short distance below the mines, the expenditures of the parties in charge having been liberal, not to say lavish, from the start.

Although the mines for the first year or two produced tolerably well they made no net earnings and finally failed to meet current expenditures. Seeing how matters were going, the

ing machinery will be required. The money invested by the shareholders proved a total loss.

The Story of the Tacoma Venture.

Another of these Utah failures, being short, is quickly told; the enterprise, in so far as bullion production is concerned, having been abandoned in its infancy. The mine bearing this name, the latter given also to the English company who bought it, is located in the Lucin district, Goshute mountains, near the Nevada line and about seven miles south of the Central Pacific railroad. The property was purchased by parties in London in 1872, and the next year outfitted with a smelting furnace having a daily capacity of twenty tons. Results not coming up to expectations the furnace was shut down after a few weeks' run. From this time on no further efforts at working the mine were made by the new owners, though it has since been worked, off and on by other parties.

During the year 1875, there were shipped from this mine to the Jordan and Galena smelters, 354 tons of excellent ore. The ownership of the property appears to still rest in the English company, though they have not had the practical control of it for several years past. There was a rumor not long since, that the company, in London, intended to re-ascend the mine, which, judged by all accounts, is a reasonably good one, and should never have been neglected the way it was. The ore here consists of the carbonate of lead, with very little sulphuret, but containing enough oxide of iron to flux it. It is a good smelting ore and carries a fair percentage of silver and lead with a little gold. The geological features of the district are similar to those about Leadville, the formation being lime and the ore masses capped with a heavy deposit of iron. Mining operations here have to be carried on under some disadvantages, the country being destitute of timber and but poorly supplied with water. These drawbacks are, however, in a measure, compensated for through the proximity of the district to the railroad. Besides the Teconathere are numerous other metalliferous lodes in the Lucin district, all carrying similar ores, and on some of which a good deal of work has been done. Although several of these lodes make a line showing of ore, the output of bullion and the ore shipments here have been comparatively limited; the entire district, for some reason or other, appearing to have always rested under a cloud. Despite this, the mines are well spoken of by many good judges who have visited and examined them, and it is probable enough that a mining enterprise set on foot here would, if well conducted, meet with success.

Timbering in Mines.—No. 9.

The Austrian Tunnel System.

A cause assigned for the sinking of the top-timbers in the early Austrian tunnels, has been insufficient propping of the face. As soon as these faces are pressed inward into the tunnel-space, the top-heading sinks. Care must therefore be taken, in treacherous or very soft ground, to hold this face well back. Finally, came the question of how to dispose of the "timbering" in its erection so as to cause each successive piece added to form an integral part of one homogeneous whole system. It has been customary, in the Austrian system, to place the upper center timbers first, and then the lower, beneath the middle sill, and this has been done even in the softest material. This, of course, necessitates undermining and underpinning the upper set after it has once been placed. If the ground is moderately firm this method may be carried out with no great trouble, but in very bad ground undermining of timber is always disadvantageous. Even a slight loosening, caused by this undermining, may shake all the timbering above.

Looking into the matter, the later Austrian engineers, and notably Mr. Rziha, have advocated the "Firstenbau," or bottom breaking in system. As thus applied, the bottom-heading is, first of all, driven throughout the tunnel, serving at once as an adit for the water, giving also free ventilation and establishing the alignment of the tunnel definitely. Then this can be enlarged to a higher and wider heading, the bottom timber of which ultimately acts as the bottom sill of the tunnel timbering; its cap is the subsequent middle sill, and its side props are the legs of the subsequent lower center frame. To strengthen this frame the horizontal longitudinal bars are placed beneath the cap, as shown in Fig. 2.

This bottom heading (Fig. 2) being completed, as a rule the ground above has been so well drained as to offer no very serious difficulties in excavation. The top-heading is then constructed, and the advantage of this method of procedure evidently lies in the building from below upward. The lower set acts as a foundation for all the subsequent work, and remains undisturbed in its position, as it was first placed. Moreover, this high heading again serves to further drain out the sides before the enlarging is begun.

This latter is commenced on the right and left at the top, and thence continued, as shown in Fig. 16. The excavation of the sidewalls is then begun, and the full excavation taken out. First 1 is cut out, then 2, then 3, and then 4. The center then proceeds downward. The main tunnel is shown by dotted lines.

This timbering of the full area of tunnel having been finished in sections of six, nine, or eighteen feet, according as the ground may permit, the masonry is begun. As the arch goes up, the props to the roof-timbers are removed, and the latter are stayed by temporary props resting on the centres, until the arching reaches them and they can safely be removed. Where the material is not too loose, the lagging also is taken out.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other
Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize
the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman
strength. On one occasion he slew several giants who opposed him, and with one blow of
his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slog Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Olan and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL,

PHOSPHATE ROCK, ETC.

It is simple and reliable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

THOS. F. ROWLAND, Sole Man'fr, Brooklyn, N. Y.

JOINT FOR SHEET METAL PIPE.

RE-ISSUE PATENT NO. 8,214 TO JOSEPH MOORE AND FRANCIS SMITH.

"The invention consists in connecting the meeting ends of the pipes firmly together and placing a bed or tube around the outside of the meeting ends, which is larger in diameter than the pipes, and which is long enough to extend a distance on each side of the joint and then filling the space between the outside bed or tube and the pipe, with a packing of lead or other soft material, either by casting or ramming." (Extract from specification of Patent.)

These joints have been tested for 8 years, and are undoubtedly the best joint made for sheet iron pipes—THE BEST AND CHEAPEST.

Any INFRINGEMENT will be PROSECUTED. FRANCIS SMITH & CO., Manufacturers of Pipe of all Kinds, 130 BEALE ST., SAN FRANCISCO.

PELTON'S PATENT Reaction Hurdy Gurdy Water-Wheel.

This Wheel will be guaranteed to purchasers to give 8% of the theoretical power of water. See "Seed for circular" to L. A. PELTON, Nevada City, Nevada Co., Cal.

QUICKSILVER.

THE CELEBRATED A BRAND.

Shipped Direct from the New Almaden Mine, New Almaden, Santa Clara Co., Cal.

For sale in any quantity. Trademark A on top of Flasks secured by United States Patent, and registered. Flasks contain 7 1/2 lbs. Quicksilver. Weight and purity guaranteed.

CARLOAD LOTS will be shipped from San Jose, f. o. b., for Nevada, Arizona, New Mexico, Montana and Idaho or Utah, or delivered at Pacific Mail Steamship Co.'s wharf, and Depot of S. P. R. Co., San Francisco, without charge. Railroad rates from San Jose are the same as from San Francisco.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

FRUIT BASKET.—Roswell E. Morey, S. F. No. 277,148. Dated May 8, 1883. This invention relates to certain improvements on fruit and berry boxes or baskets, which are composed of thin wood shavings, or veneers crossing each other at right angles on the bottom, and having their turned-up sides united at the top. These upper edges are united in various ways to insure strength and sufficient rigidity by wires, continuous strips of metal, etc. This invention is designed to utilize short strips of sheet metal in the construction of baskets of a considerable size; and it consists of a strengthening strip of metal clamped upon each of the four sides, and enclosing at their meeting angles, wires, either short or continuous, which are properly bent and secured by crimping the metal upon them.

CHURN.—Herman Baldridge, Los Angeles. No. 277,103. Dated May 8th, 1883. In the operation of this churn, the peculiar form and position of the dasher revolving on a horizontal axis in a vertical vessel, when taken in connection with the curved sides of the vessel, a particularly advantageous effect is produced, in that the cream is not dashed against the maximum resisting surface, as would be the case if the vessel had flat sides, but is rather swept around the curved surface, following the direction imparted by the wall of the vessel, and is thus not beaten so severely as to injure the texture or grain of the butter, and at the same time the operation of the driving crank is rendered easier.

REMOVING TIRES.—Nelson B. Hervey, Santa Rosa, Cal. No. 275,909. Dated April 17, 1883. The device is intended for removing tires from wheels, and it consists in a leveled disk or roller upon which the edges of the tire rest, and in a pressure-roller adapted to impinge upon and force down the felly of the wheel. Means for vertically adjusting said pressure-roller and causing it to rotate, complete the invention. The usual manner in which tires are removed is by hammering. This, besides being very laborious, sometimes splits the felly and otherwise injures the wheel. The object of the invention is to remove the tire by a steady pressure, applied in the most advantageous manner, and with the exercise of small power.

BUCK SAW.—Edward A. Learned, S. F., assignor of part interest to H. S. Dunder and H. L. Welch. No. 277,141. Dated May 8, 1883. This relates to certain improvements in saws of that class, known as buck saws, in which the tension of the saw is maintained by the constant action of a spring frame or spring attachment. In this class of saws it is extremely difficult to force the end frames together and hold them while the pin is being put through the frame and saw to hold the latter in place. This invention is designed to obviate the difficulty by the use of a spring latch or latches, which open to admit the end of the saw-blade, and then engage with suitable notches therein so as to hold the saw firmly when the strain is again brought upon it.

A Curious Incrustation Preventive.

A very great number of mechanical and chemical means have been tried to prevent the incrustation of steam boilers. One would be surprised to learn the variety of substances which have been employed to that end, some of them quite curious in their nature to be applied to such an object. It has remained for a California inventor, however, to be the first to utilize the eucalyptus in this connection, which adds another to the various uses to which this very useful tree has been put.

The invention consists in introducing into the boiler an infusion, decoction or other preparation of eucalyptus, either the wood, bark, leaves, blossoms and capsules, or any part which will produce the desired effect, said infusion either made separately, and afterwards introduced into the boiler, prepared in the feedwater prior to its introduction into the boiler, or prepared within the boiler itself, so as to remove any scale which may have been already formed, or so as to affect the water as to prevent the incrustation of the boiler by any substance which may be held in solution or suspension in the water, and at the same time avoid any injurious effects to the shell of the boiler.

There are many modes of applying the eucalyptus, such as boiling the leaves or other parts, making a cold infusion, or in other ways extracting the desired substance, which may be afterward introduced to the boiler, as required, either with the feedwater or by a cnp or chamber into which it may be placed, and by suitable cocks admitted to the boiler; or the leaves may be put in a receptacle and put in the boiler. The charge to be used and the frequency of renewal depends on the size of the boiler and the character of the water used, this being easily determined by inspection.

Of course, the inventor is aware that tannin or tannic acid is inherent in the eucalyptus, and that tannic acid in various forms has been used to remove scale. But tannic acid injures the boilers in the absence of any other element to counteract the effect of the tannic acid on the metal after it has performed its work on the scale. He does not pretend to give any theory of the chemical action of the eucalyptus, but he has demonstrated to his own satisfaction and that of others, by long continued experiments, that the eucalyptus will remove scale from boilers, or keep them free from scale without injuring the shell of the boiler itself, and will also prevent any rust or corrosion.

The inventor of this process is George Downie, of Salinas, Monterey county, who has just received his patent through the MINING AND SCIENTIFIC PRESS Patent Agency. Mr. J. McGilivray, of Oakland, is associated with him, and patents have been applied for in Great Britain, Germany, and other foreign countries, so highly important is the invention considered. A company is to be formed to extract the acting elements from the substance by steam process, and prepare the extract for foreign shipment. California is the only part of the United States where the eucalyptus family flourish, which they do here as well as in their native home, Australia. Where frosts occur, however, the tree does not do well.

We are informed that this substance has been applied with great success in very many places. In some cases where applied, the sediment has dropped off in pieces, and in others it has precipitated like a thin paste or mud. This seems to depend on the water. Some eleven months have been passed in trying the various experiments which have been made.

In Salinas, where the remedy was discovered, the water is very bad for boilers, so much so that the railroad people will not use it in their engines. Yet the inventor states that it has removed scale from boilers there, and prevented its forming. At the Buckeye mill, Marysville, it was tried to remove the scale from three old boilers, and put into two new ones to prevent any forming, all supplied from the same heater where the leaves are applied, and, Mr. McGilivray tells us, it acted equally well in both cases. In a number of boilers in this city it has been efficient, notably at the Baldwin hotel, where the well water caused rapid incrustation, and nothing had heretofore been able to remove the scale.

The hoisting works of the Alaska mine, at Pike City, Sierra county, were destroyed by fire last week. This disaster will prove a serious set-back to the company.

A good medicinal tonic, with real merit, is Brown's Iron Bitters, so all druggists say.

News in Brief.

EIGHT hundred emigrants, assisted by the government and Tukey's committee, embarked at Galway, for Boston, on Saturday.

THE Canada Pacific Railroad will be completed by December, 1886, which is four years earlier than the contract stipulates.

It is reported the Cree Indians are preparing for a war to avenge their losses during their late horse-stealing raid into Montana.

THE Digger Indians of Placer, Nevada and El Dorado counties are about to hold their annual conclave of mourning for the dead.

IN New York the local steamboat inspectors refuse certificates to ferry-boats that store their illuminating gas in tanks in their holds.

It is reported from Salt Lake that an extension of the Union Pacific will be made through central and southern Nevada to California.

The various potentates of Europe and Asia are slowly converging to Moscow to participate in the coronation festival at the end of the month.

It is announced that negotiations are pending between the Union and Central Pacific for bringing overland trains six hours earlier into San Francisco.

THE sensational developments of criminal practices in the opium dens of New York have led to an investigation of similar dens of iniquity which infest Chicago.

THE building boom in Great Britain is marvelously prosperous, and railway construction seems to be almost feverishly active. Public works are starting up everywhere.

THE present is the severest spring ever known in Nevada, and vegetation is at least six weeks backward. There will be fine pasturage, however, when the grass does get a fair start.

THE Brooklyn Bridge Trustees have fixed the fare for foot passengers at one cent. The disbursements thus far on account of the construction of the bridge amount to \$14,689,905.

THE Mountain View Immigration Society has been organized by colored residents of Stockton. The Society has for its object the bringing of negroes from the Southern States to the Pacific coast. The men are for farm laborers and the women for house servants.

THE Trustees of Columbia College, New York, have prepared a plan to receive young women for a four years' course outside of but under the supervision of the college; graduates to be entitled to the same honors as the young men who have taken the regular course.

It is stated that there is to be a scarcity of cocoa. The rebellion in Ecuador has prevented the natives from gathering the cocoa crop there; the revolution in Hayti has reduced the crop in that restless island, and in Colombia dry weather and grasshoppers have destroyed the entire crop.

THE trestlework railroad bridge now being constructed across Lake Pontchartrain will, when completed, be twenty-one miles in length and will be the longest bridge of the kind in the United States. More than 15,000,000 feet of lumber outside of the piles will be used in its construction.

W. W. McCoy, of Corral de Tierra, says the Salinas *Index*, has a well that goes dry during the rainy season for about three months, while in the dry season it constantly flows a stream of pure water. Within three rods of this spring is another from which an abundance of water runs the year round.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct, or if the paper should ever come beyond the time desired be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time, we cannot be responsible for the errors or omission of agents.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

Our Agents

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

For WET or DRY Crushing.

SIMPLE, EFFICIENT and DURABLE.

The Balls revolve horizontally without friction. 5 ft. size, weight 1,000 lbs., and does more work than 15 Stamps, 3 ft. size, weight 1,500 lbs. Concentrating Mills, Rock Breakers, Amalgamating Pans and Separators, Roasting Furnaces, Hoisting and Pumping Machinery, Engines and Boilers, any size required. Hydraulic Cylinders and Pumps, Ore Cars, Ore Buckets, Safety Cages, The Hard Power Two-stamp Mill weight 250 lbs. THE EUREKA WIRE LOPE TRAMWAYS, Concentrating Riffles for Mills and Hydraulic Sluices.

Agents for INLAY ORE CONCENTRATOR and the

California Quartz Mines.

The *Daily Transcript*, Nevada Co., Cal., says: Interviews with many of the mine owners and employes in mines, show the quartz mining interests of this locality to be particularly prosperous at this time. From one end of the district to the other the industry is enlarging, and yet not one out of a hundred of the good claims are developed. In illustration of the assertion that the development of our resources in that line has scarce been begun, we desire to call attention to the impressions of a gentleman who, about a year ago, came here from the East to examine a particular quartz mine in this township. He remained here several days after attempting to his special mission, and no part of the district was left unnoticed by him. On the day of his departure, in conversation with one of our mining men, he said: "Let me tell you one thing. I have visited every mining center on the Pacific coast, as my special business is to make a thorough examination of properties for Eastern capitalists, and I assure you that in my judgment, the outlook for an immense mining industry in Nevada City is second to that of no other district. The whole surroundings indicate a vast network of ledges that will take ages to work out. Why, sir, there has nothing been done around here in the way of opening up the immense wealth that lies buried in the ground. Instead of there being eight or ten mills running, I believe that within ten years there will be eighty or a hundred, and they will all be doing as well, if not better, than those at work now, provided you can get capital in here to take hold of your mines. This district is bound to come to the front, and the fine prospects should entice capital to your doors. There is something substantial about your mines that we seldom find in other sections. They are lasting, and that is what is going to keep up your town and make property very valuable here for years to come. This district has been scratched over a little, and that is about all that has been done in the way of quartz mining. If there never had been any Comstock, Nevada City and Grass Valley would now have a population of ten or fifteen thousand apiece instead of six or seven thousand, and these hills would be alive with men. Never mind, my word for it you will see it yet."

The gentleman referred to is no enthusiast, but cool, clear-headed and scientific, as well as a practical miner, and his words were well considered. The quartz interest has been growing slowly for the past five or six years, and each year as it rolls by shows an increased bullion shipment and new mines added to the list. There is no excitement here, but everything goes along quietly, and the large number of men employed shows that the mines are in a healthy condition. There is not a mine in the district that is a stock gambling proposition, but all of them are owned by men who have personal supervision of them. The amount of gold taken out, or the profits, are known to no outsider, and we may say that is one great reason why Nevada City does not with the outside world assume the high place that it actually deserves. If the whole truth about the mines was published in the local papers, where one dollar is brought here for investment there would be thousands; but the owners take the ground that they are conducting private business enterprises, the same as a grocer or dry goods dealer, and the public has no right to ask for a statement as to the results. Their mines are not for sale, and they have as great a dislike for having an impression go out that there is any attempt to "boom" the properties, as a hen does for a swim in a mill pond. Such a course acts as a barrier in keeping capital away. For instance, an attempt is made to sell a mine to parties who are not familiar with this section. The first question asked is, "Have you any paying mines in this district?" The reply is, "Yes; such and such mines." "How much do they take out per month or annum, and how much does the best and poorest rock pay?" "I don't know exactly, but know that they pay largely for the investment." That is about all that can be said, and its very indecency gives rise to a suspicion of something wrong, and scares the capitalist into giving the district a wide berth. If the situation of our mines could be given to the public as at Virginia City, Bodie and other places, Nevada City would be as familiar a name all over the world as any mining camp on the coast. The Idaho mine is the only one in Nevada county that publishes its dividends, and everybody knows there are a number of others that are paying comparatively as well.

SMELTING FURNACES.—The Southwest *Scientist* (New Mexico) says: Messrs. Fraser & Chalmers have recently taken the contract for all the material to enlarge the works of the Benson Smelting & Reducing Company of Benson, Arizona Territory, composing two water-jacket galena smelting furnaces and all material and machinery necessary to complete them. These works are the most successful west of Denver; they are managed by Carl Henricks a metallurgist of great experience and ability. Fraser & Chalmers have also been awarded the contract for furnishing the boilers and motive power complete to drive the electric machinery for the Brush and Swan lights now being placed at Albuquerque, New Mexico, for lighting the city and suburbs.

CARE-WORN persons, students, weak and over-worked mothers will find in Brown's Iron Bitters a complete tonic, which gives strength and tone to the whole system.

Oh, My Back!

That's a common expression and has a world of meaning. How much suffering is summed up in it.

The singular thing about it is, that pain in the back is occasioned by so many things. May be caused by kidney disease, liver complaint, consumption, cold, rheumatism, dyspepsia, overwork, nervous debility, &c.

Whatever the cause, don't neglect it. Something is wrong and needs prompt attention. No medicine has yet been discovered that will so quickly and surely cure such diseases as BROWN'S IRON BITTERS, and it does this by commencing at the foundation, and making the blood pure and rich.

Wm. P. Marshall, of Logansport, Indiana, writes: "My wife has for many years been troubled from pain in her back and general debility incident to her sex. She has taken one bottle of Brown's Iron Bitters, and I can truthfully say that she has been so much benefited that she pronounces it the only remedy of many medicines she has tried."

Leading physicians and clergymen use and recommend BROWN'S IRON BITTERS. It has cured others suffering as you are, and it will cure you.

THE ROLLER ORE FEEDER.

Patented May 28, 1882.

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required. In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

HORIZONTAL AND VERTICAL ENGINES
1 to 100 Horse Power.

MINERS' HORSE-WHIM

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The standard of the whim is bolted to bed-timber, thus avoiding all frame work. When required these whims are made in sections to pack on mules.

NATIONAL DUPLEX COMPRESSOR.

KNIGHT'S
Mining Water Wheel.
OVER 200 IN USE IN CAL.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,
—OR—
VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinkley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringers.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

Room 7, 109 California Street,
Nov. 6, 1882.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts

Small Sizes made in Sections not to Exceed 300 lbs.

Price's San Leandro Village Carts.

Phæton Style, with Calash Top.

Piano Box, without Top.

What People are Saying about San Leandro Village Carts:

The following extracts from letters are samples of what I am constantly receiving, and not one of them was solicited, but are merely incidental portions of correspondence about sales:

SALINAS, Dec 11, 1881.
FRIEND PRICE:—The cart came all right. Have driven around town a little, and am much pleased with it. I think it a success, and ought to make you a fortune. Now turn yours if loose and make me something handsome, with pole and shafts, full lazy rack, etc. (Here follows specifications, etc.) Also send me one grade A. phaeton style.
Yours truly,
PARIS KILBURN.

LAKEPORT MILLS, April 5, 1883.
MR. JACOB PRICE:—I was in S. F. a few days ago and purchased one of your carts, and I like it first-rate. I think I can sell several here. If agreeable will act as your agent in this place. Respectfully, etc.,
M. STARR.

SACRAMENTO, April 14, 1883.
JACOB PRICE, San Leandro.—Dear Sir: Cart received. All O. K. I consider your guarantee (as to riding qualities and remaining level) fully sustained in every particular. In fact, I have never ridden in any but more easy. It is superior to anything I have seen here in Sacramento, and that is saying a great deal, for there are five different makers. Anything I can do to aid you in making sales I shall do cheerfully. I send you \$100 by Wells, Fargo & Co. Yours truly,
F. M. PAGE, Int. Rev. office, Sac.

POINT ARENA, Apr. 16, 1883.
MR. J. PRICE.—Dear Sir: I have now used the cart I purchased of you some days, and find it all anyone could wish for, and can say it is the BEST ONE MADE, as I think I have seen them all. I have to get out frequently and let parties try it, although I do not exactly like to do so, but I make that all right. I think you will receive at least 20 orders during the next few months from parties who have seen mine. I know four already who will call on your agents in the city the first time they visit the bay. Yours truly,
R. B. PHILLIPS.

GUARANTEE:

All of my Village Carts, of all grades and styles, are warranted to be wholly free from that annoying and ludicrous bobbing motion common to other two-wheeled vehicles, and to be so constructed that they can be instantly made level, whether a large or small horse is used or a light or heavy load is carried, and to ride as easy as the best buggy.

GOLD QUARTZ and PLACER MINERS'

Silver Plated

AMALGAMATING PLATES,

For Saving Gold.

Every description of plates for Quartz Mills and Wet or Dry Placer Amalgamator Machines made to order, corrugated or plain.

OVER 2,000 ORDERS FILLED.

The most extensive and successful manufacturer of these plates in the United States. Will fill orders for delivery in Rocky Mountain and Pacific Coast Mining States at lower prices than any other manufacturer.

Old Mining Plates Replated. Old Plates bought, or gold separated for low percentage of result.

SEND FOR PRICE LIST.

SAN FRANCISCO PLATING WORKS,

653 & 655 Mission St., San Francisco, Cal.
E. G. DENNISTON, Proprietor.

EXCELSIOR BLASTING POWDER,

Manufactured by the

EXCELSIOR POWDER COMPANY.

This is no new, patent, non-explosive Safety Powder, but the Genuine Standard Nitro-Glycerine Powder, as safe to use and handle as any other Nitro-Glycerine Powder manufactured. The fumes and gases, common in nitro-glycerine powders, are destroyed, and do not leave the miner with headache or nausea.

The powder is put up in cartridges of any size to suit the consumer, and is exploded in the same manner as all other high explosives; that is, by means of cap and fuse, or by electricity. It is not claimed for this powder that it is a non-explosive, or safer than other nitro-glycerine powder. All powder, and especially nitro-glycerine powder, should be handled carefully. The EXCELSIOR POWDER is as safe, and for strength far surpasses any other powder on the market. Address all orders to

EXCELSIOR POWDER COMPANY.

Number 21.

Lodes in Placer Claims.

Although numerous instances have occurred where ledges have been found in placer claims, there are a number of legal questions involved where such circumstances exist, that have not been settled. The United States Land Office has lately been dealing with some of these. In one case where a patent was issued for a placer claim as far back as 1876, a lode claimant applied for a patent on his lode claim within the limits of the placer claim, in 1880, alleging that the lode was known to exist at the date of application of the placer claim. There was conflict of opinion on the question of whether the lode was known to exist at the time of the first application. A hearing was had to determine the question, and the Register and Receiver found from the testimony that at the time of the issuance of the placer patent, January 14, 1876, there was no "known ledge or quartz lode, or other rock in place bearing gold, silver, tin, lead, tin, copper, or other valuable deposits." And upon appeal to the Commissioner of the Land Office, that official reviewed the testimony and affirmed the finding of the local officers.

When the Land Office directed the inquiry to be made as to whether the lode was known to exist at the time of the placer application, the lode claimant swore the placer claimant knew at the time it did exist. Now comes the Secretary of the Interior and says that this brought the case within the rules established by the Department in the late case of Becker vs. Sears and War Dance lode vs. Church Placer, in which it was held that the lode must be known to exist at the time of application. He directs that all proceedings subsequent to the lode claimant's application for patent be dismissed without prejudice, and that the lode claimant be permitted to proceed in compliance with the statute. The adverse claim can then be made and the controversy settled by the court. The lode claimant's application was rejected on the ground of conflict with the patented placer claim.

California Iron.

The furnaces of the iron mines at Clipper Gap, Placer county, in this State, began turning out iron this week, which is now being shipped here. It will be remembered that some months since, by an explosion and fire at the works, a serious loss was incurred, and that the works had to be rebuilt. The owners were not discouraged, however, but went ahead, and now they have everything running again.

This is the only iron mining we are doing in California, although iron is found in many parts of the State. The Clipper Gap iron is first-class, and is purchased as fast as produced. Arrangements are now being made at the Judson works to put up the necessary works to make wrought iron of the pig from these mines. The rolling mills already built there will be extended as soon as iron can be supplied for them from this source, and it will not now be long before this is done.

It is in industrial enterprises of this character that much of the future welfare of this State depends. We have been dependent for iron on our imports, and this home product will be of great assistance. Of course, this mine cannot nearly supply the demand. Still, it reduces the importation appreciably. The new furnaces work well, and the iron turned out is "No. 1" in every respect. It is to be hoped that it will not be very long before other iron deposits in this State will be developed, so that some time in the future we will be independent and be able to produce all our own iron.

Huntington's New Crushing Mill.

Frank A. Huntington, of this city, has devoted considerable attention of late years to mining machinery, and especially ore-crushing appliances. He last week obtained a patent on a new crushing device through the MINING AND SCIENTIFIC PRESS Patent Agency, and which is illustrated in the accompanying engraving. It

be replaced when worn out. These shoes may be made of cast iron, but the large interior die *G* of the pan is of wrought iron, because it will wear smoother and not become chipped.

The rollers *b*, have vertical stems or shafts *c*, to which they are fixed vertically and the shafts extend up into or through sleeves *f*, in which they are fitted to turn. These sleeves have horizontal trunnions which turn in boxes on the

HUNTINGTON'S CENTRIFUGAL ROLLER QUARTZ MILL.

consists of a pan having an interior circular die around its periphery, and, in combination with this, of a series of rollers, which roll against the die, being suspended by vertical shafts turning in sleeves which have horizontal journals above, so that the rollers may swing rapidly. The suspending mechanism is supported upon a cross or frame, which is driven by a central

frume which is keyed to a central shaft. Scrapers serve to lift the material from the bottom of the pan as the rollers do not touch the bottom of the pan, so that it will be carried between the roller and the die until sufficiently fine to pass through the screen. The rollers are allowed to swing to and fro from the center of the pan, and when the frame is rapidly ro-

PRIMITIVE METHOD OF GRINDING ORE

shaft, and the rollers are thus thrown outward against the die by centrifugal action.

In connection with this apparatus, Mr. Huntington employs scrapers, which are carried around by the frame and throw the material to the outside, where it will be acted upon by the crushing rollers until it is fine enough to pass through the screens on the sides of the pan above the crushers, as shown in the cut.

The engraving shows a portion of the pan broken away so that the mechanism can be understood; *b* represents the rollers, which have cylindrical shoes surrounding them, which may

tated the rollers will be thrown outward by centrifugal force so as to crush anything which may pass between them and the die, *G*, surrounding the inside of the pan. The ore is fed through a hopper, *h*.

Mr. Huntington says that this mill has worked very well at the Whidder mine, El Dorado county, in this State. It is constantly crushing, and has a good discharge. The cost of erection and freight are small. He says, also, it is a very good amalgamator, saving fully nine-tenths of the gold in the mill.

CALIFORNIA capitalists have purchased thirty-six sections of railroad land northwest of Sprague, W. T.

Influences on Shots in Blasting.

Blasting may be defined to be the rending or tearing apart of any solid body, by the pressure or shock exerted upon it from the sudden development of gas of high tension, evolved on the ignition of some explosive compound placed contiguous to it. This is the definition given by Drinker in his work on "Tunnelling." As the drilling of the holes may be said to be the dearest part of blasting it follows that great care should be taken in setting each hole in such a position, and in drilling in of such width and depth, as to insure the greatest effect at the least cost. When the many circumstances which may influence the effect of a shot are recalled, it is evident that the proper setting of a hole is a matter rather of practice based on experience, than one to be decided by empirical rules, for even were a set of rules deduced from experiments in one material, they would only apply, under similar circumstances, in the same material. The effect of a shot may be influenced, among other considerations, by:

1. The shape in which the rock is presented, the size and number of the open faces, the shape of the piece it is desired to take out, if that is an object, and, of course, primarily, in the size of the cross section of the face if it is heading work.

2. The texture of the rock, whether it is hard or easy, firm or loose, brittle or tough; thus experience gained in blasting close grained, hard granite, trap, gneiss, etc., would not apply to sandstone, limestone or slate.

3. The structure of the rock, as to whether it is stratified, laminated or fissured; upon its cleavage, etc., and upon whether it is massive or broken.

4. The elasticity of the rock.

5. The explosive used.

6. Whether the hole is to act alone, or simultaneously with, or following others; and in the case of simultaneous firing, the question arises of how the waves of oscillation will best act in concert.

7. The character of the fuse and tamping.

Working Ore.

An engraving on this page will be recognized by many as the means employed in Mexico very extensively, and in Arizona, New Mexico and California, more or less, for working ores. The apparatus is a very simple one to make, and a couple of mules furnish the motive power. Arastras, Chile mills and appliances of similar construction are very good amalgamators and work much closer to real value of ore than more complicated machines. But they do their work slowly. Perhaps, however, time is an element of success in amalgamation more than is generally recognized. The American plan is to work the material through as quickly as possible; but Mexicans do not value time so much, so perhaps they get better results on this account.

TIMBER ON MILL-SITE.—The Commissioner of the General Land Office has given the following opinion: "If the mill-site claim is timbered, there would seem to be no good reason why the lawful claimant should not be permitted to cut and remove the timber thereon for the purpose of constructing a mill, reduction works, tramways or other accessory required in the development of his mining interests. In permitting the removal of the timber from such mill-site or tract of non-mineral land prior to the issuance of patent therefor, it is strictly forbidden to make such timber an article of sale for private gain or speculation."

Early History of the Comstock—No. 4.

EDITORS PRESS:—Claimants are becoming quite numerous for "who made the first assay of Comstock ore?" I desire to say, that from my own knowledge the first ore assayed was by H. W. Theall & Co., in Marysville, Cal., in May, 1859. The ore was brought from Washoe by one Elija McCurdy, who, after knowing the results, went to Nevada City, and remained there until the last of June, when, in company with Shep McFadden, Sam Beard and Bart Kinch, they arrived here on the 9th of July, and entered into a contract with Len Savage and Chase, to run a tunnel for one half of the ground, which contract was completed, and is well known to old Comstockers. All the parties sold out their interests for considerable sums. So as you see, if Dr. Linsweert's friend, Major R. Killalee, did not bring his ore to San Francisco until July 28, 1859, he was behind some time. The Savage tunnel had been run one hundred feet by that time and ore had been shipped to Sac, via Placerville, from the croppings of the Ophir. In July it was an "open secret" in Marysville and Nevada City, that silver ore had been discovered, and in August Johnny Newman had completed his house, and by September had killed an Irishman, who was known as Sailor Jack, formerly of Forest City, Cal. So you will see the Doctor is "off."

ROBERT G. LOWERY.

Virginia City, Mar. 15, 1883.

Arizona Outlook.

The Arizona Gazette says: The interest in mining affairs throughout this Territory has less of the sensational, and far more of the practical and lasting about it, than we have ever previously known. In Yavapai, Mohave and the counties south of us, this industry is being prosecuted with vigor, and our own county, although she bears the name of being the leading agricultural section, is not far behind in the matter of her mining industries. New and rich mines are being discovered in the districts north of us, and it is but a question of time before we will lead the most favored sections of our Territory in the production of the precious metals. Castle creek, with its immense and rich deposits of copper and silver, will soon be added to the list of producers. Cave creek, Winifred, Magazine and other districts equally as rich, have felt the depressing effects of bad management; many mines in which, were forced to shut down.

This state of affairs has happily been relieved by a general change of management; men of good sense and practical mining experience have entered into the business with a view to fully develop their properties and put them on a paying basis. Confidence in the richness of their mines is gradually but surely returning, and all that is needed to confirm this is the erection of reduction works. As soon as these facts are known, and are found to be reliable, the money which now lies molding in the safes of capitalists waiting for investments will circulate in this direction, and we will then enter upon an era of stable prosperity hitherto unknown in our Territory. To persons seeking investments in mines of worth, we cordially extend an invitation to visit the mineral resources of Maricopa county.

A NEW FIND.—The Exchange mine at Monte Christo, was one of the richest drift claims in that section in early days, and the ground was supposed to have been thoroughly prospected and worked out. It seems, however, that several experienced miners, known as Thatcher & Co., have been engaged in looking for a possible bonanza in the old claim for some time past. People know more about drift mining now than they did twenty years ago, and in this instance a fine prospect is encountered in a mine that was virtually abandoned by former owners. Thatcher & Co. merely raised up about forty feet above the old workings and discovered a new channel. Our informant says that the new channel has every appearance of proving extensive and rich. There are numerous other so-called worked out gravel claims in the county that experienced prospectors might do well to try by paying a little attention to them.—*Sierra Tribune*.

BORING FOR GOLD.—A new plan of prospecting for placer gold is by using an auger of a peculiar form that bores a hole about three feet in diameter—indeed, what might be called a shaft. Speaking of an operation of this kind, the *Plumas National* says: The work of boring Mills' big shaft is going steadily on, and about 156 feet of tubing is now in. The borer goes down from two to three feet per day, and for the past two weeks has been cutting through a beautiful bed of blue gravel, which contains some gold. There are many indications that the bedrock will show good pay, and the best miners who visit the shaft are highly pleased with the character of the gravel.

The agent of the Gold Stripe Mining Co., Plumas county, expects to be able in a few days to make a proposition to parties who have claims against the property, to offer fifty cents on the dollar, in liquidation for the same. If this offer shall be accepted it is likely that operations will be begun at the mine without delay, otherwise, he says, nothing may be done this summer.

The Coming State.

The Resources of Washington Territory.

Governor Newell, of Washington Territory, while at the national capital as a commissioner, delegated by various municipalities, corporations and prominent citizens, to urge upon Congress the early admission of their Territory as a State, was interviewed by a reporter of the Washington Post and asked what claims, other than the one of 125,000 population, he would urge.

"I cannot reply better than by stating what our resources are, and thereby demonstrating our ability to sustain ourselves as a State. We consider that we have the ability to assume the functions and bear the expense incidental to Statehood."

"What are these natural resources upon which you base your claim to be self-sustaining?"

"Leaving out Alaska, Washington Territory is the extreme northwestern possession, and lies between the Pacific ocean and Idaho, British Columbia and the Columbia river. It contains 70,000 square miles, aggregating 450,000,000 acres. It is divided by the Cascade mountains, an extension of the Sierra Nevada, which run nearly north and south into two separate regions, differing essentially in their characteristics, and called respectively east and west Washington. The latter occupies about two-fifths of the Territory, and is known as the Puget Sound basin. The surface is hilly and in some portions mountainous. Four fifths of this surface is covered with dense forests, the trees being of great magnitude. They consist of white and yellow fir, cedar, hemlock, spruce and pine, with smaller quantities of ash, elder, oak, pine and maple. The fir tree especially reaches, when full grown, an enormous size, the average tree measuring four feet with an altitude of from 250 to 300 feet. Many monstrous specimens are found, some fourteen feet thick. This variety is found nowhere outside of Vancouver's Island, Washington Territory, and Western Oregon. It is highly bituminous, tough, elastic and enduring, and especially adapted to the construction of naval vessels in all their parts."

"Have you nothing but trees, Governor?"

"We have other resources equal in value to the wood, which I will tell you about after I have told you about the huge cedars we have. We have gold, silver, copper, zinc, cinnabar, tin, plumbago, mica, soapstone, marble, granite, sandstone, and limestone; all these are found within our limits. To utilize our timber, saw mills of large capacity are operating upon Puget Sound, the largest of which is at Port Ludlow, a new structure, complete, but not yet in operation, being 436 feet long and 200 feet wide. It has a cutting capacity for 218 foot logs. The amount cut last year was 35,000,000 feet. This is sent to the Pacific coast, Asia, Australia, France, England, and the Nile. There are 12,000,000 acres of such timber, worth hundreds of millions of dollars. There are cedars in existence twenty-one feet in diameter in all parts of the Territory. The bark of the fir tree is used mainly for fuel. The forests are filled with elk, deer, bears, foxes, rabbits, grouse, pheasants, ducks, and other game."

"Have you any coal deposits?"

"Gen. McMicken, the Surveyor-General of the Territory, informed me in a recent interview, that the entire Puget Sound basin is underlaid with coal. The indications are apparent everywhere. The varieties are bituminous, lignite and anthracite. Extensive mines have been opened at Seattle, Tacoma, and along the line of the Northern Pacific. The mines at Seattle and Tacoma are extensively operated, each town having facilities for loading vessels at the rate of 1,000 tons a day, the mines being located within one hour of rail communication from the bunkers, at which the vessels are laden. Four steamships of 3,000 tons capacity are already established upon a line which supplies Oregon and California. Five more are to be added."

"What else have you?"

"About 7,000,000 of acres of Puget Sound basin is easily convertible to the best agricultural and grazing lands. The river bottoms, the heavier dam meadows and other alluvial deposits furnish a soil of inexhaustible fertility. The islands of the Sound are also highly productive, and indeed the entire surface of the country, when denuded of its timber, if that day could arrive, is especially well adapted to grazing and grain raising. White clover seems to be indigenous to the soil, and is absolutely irrepressible in its growth wherever the sun shines upon it. But the great agricultural and grazing portion lies east of the Cascades, the great plateau of the Columbia. Here are 30,000,000 of acres of land—prairie land—undulating and mountainous, mainly bare of vegetation, save sagebrush and bunch grass. Nearly all of this country is capable of producing, under proper cultivation, prodigious amounts of wheat, rye, barley, oats, flax and cultivated grasses. The census report indicates an average wheat crop of twenty-seven and a half bushels to the acre, the largest average yield mentioned there. I have seen a field of 2,000 acres which yielded an average of thirty-five bushels. Of these 1,000 acres averaged fifty bushels. The season for seeding extends nearly equally well from October till May, and for harvesting, from July to December. The straw being firm and strong, stands, and the hull, being firm, prevents the grain from falling out. During last season, 250,000 tons of surplus wheat were sent out of the Territory, and the estimated production for the next three years is 350,000 per year. Not

one acre in a hundred, even then, will be under cultivation. The grain is especially adapted for export, not being injured by transportation."

"What kinds of fruit grow in your would-be State?"

"Fruits grow luxuriantly to great perfection, and many native to warm latitudes, such as prunes, etc., grow well. Vegetables also grow exceptionally well. Stock is raised extensively; beef cattle, of which 250,000 head were exported last year; dairy cows, sheep and swine all thrive and prosper."

"How about your coast line?"

"Washington is destined to be a great maritime and commercial center of the Pacific coast. Puget Sound, the great Mediterranean of this continent, covers an area of 20,000 square miles, has a shore line of 2,000 miles, an average width of seven miles, and a depth of thirty to 200 fathoms, which is free from rock, bar or shoals. It ramifies through the main portion of Western Washington, furnishing easy and safe outlet to the world for the products I have told you about, and also communication. The rivers afford inland navigation of 2,000 lineal miles, the chief being the Columbia, which runs north-west 200 miles through Eastern Washington, bearing the waters which drain an area of 400,000 square miles. Seven hundred miles of railroad are already built. The Sound is connected with the Columbia, and connections will soon be made with the Atlantic and seaboard by means of the Northern Pacific, which will be completed this fall, 300 miles only having to be constructed, two hundred miles of the road bed for which is made. These waters are inhabited by salmon, halibut, trout, cod and eighty other varieties of fish; \$3,000,000 worth of salmon was canned last year on the Columbia river."

"Have you any towns, Governor?"

"The towns are comparatively small. The chief of these are Seattle and Walla Walla. Other towns exist elsewhere, and many are springing into existence. Churches of the various denominations to the number of 300 are in full operation. The system of education is simple. Sections 16 and 31 of every township are donated by the Government for school purposes. A university is in successful operation in Seattle. There are eight daily and thirty weekly papers, all conducted with decency and ability."

"The finest climate in the country?"

"The climate is the most remarkable feature of western Washington. The thermometer during the winter averages forty degrees above zero. The summers are delightful, being free from heat, thunder showers, or other evils and inconveniences that attach to hot climates. The scenery is grand, the Olympic and Cascade ranges being 15,000 feet high, with many others of nearly equal altitude, covered with eternal snow, present scenes of grandeur not surpassed elsewhere."

"No drawbacks to this Arcadia?"

"There are two things that might be considered so. There is a wet and a dry season, the former extending from January to March. This is considered by some people disagreeable, but it is essential to the great vegetable productions. High winds also prevail in Eastern Washington. These are the only complaints I have heard in a residence of three years. A country more agreeable in its personal surroundings has yet to be discovered, so far as I have experienced."

"And you want to be a State?"

"The people are especially desirous of availing themselves of the advantages of Statehood, being conscious of being able to sustain themselves and do honor to the Union."

Black Hills Copper Mines.

For four or five years past attention has been attracted to wonderful copper and silver lodes about twenty-five miles northeast from Prescott, in the Black Hills, but not until within the last year has any considerable work been done in that section with a view to their proper development. Mr. Ruffner, some four years ago, located several ledges, and made an effort to induce gentlemen of means to take hold and assist him in examining their true merit, but in this he was unsuccessful. Again about one year since he made an effort and was more successful, as Hon. Hugo Richards had expended some means in finding out that heavy bodies of ore actually existed in the Black Hills, and it was then that Gov. Tittle and Prof. Thomas went in there and satisfied themselves in the premises, and purchased the interest of Mr. Ruffner, and went to work properly developing the property. To-day over 100 men are at work building a road into the copper fields, and machinery manufactured at Chicago upon patterns of Rankin & Brayton, of San Francisco, has been purchased, and is now at Ash Fork, within fifty miles of the mines, awaiting the completion of the road, when it will be placed in position, and bullion by the wholesale will be the result. In this district, other well-known gentlemen own several of the gilt-edged mines, among whom is Lieutenant Kingsbury, now of Fort Mason, near San Francisco. The works going on will bring these outside properties into prominence and open an avenue for their development.

It is thought that the road will be completed the next sixty days. Those who have seen this property agree with Prof. Thomas that it is very valuable, and justifies the outlay in making the costly improvements now going on, or in the words of Col. Sellers, "there's millions in it."—*Arizona Miner*.

Marysville.

The Salt Lake Tribune says: From time to time much has been written and said in regard to Marysville being the center of a large mining and mineral section, and as possessing vast reserves that only need a more thorough development to place it among the leading ranks of ore-producing communities. It would seem, from a critical examination of all the geological conditions which go to make up vast mineral areas, that this region was pre-eminently fitted to become, in the near future, one of the leading ore sections. Such being the case, the question naturally arises, why is there not a better showing given at the present time on some of the leading properties in the way of shipments of bullion output, and why is there not more capital invested?

As an answer to the first, it can be said the owners are quietly working away on some of the leading mines, not wishing to make much noise as the developments progress, preferring to make sure before commencing the reduction of the ores, that they have true and permanent mines, and that plenty of ore may be on hand, so that the run for its reduction may prove continuous.

As an answer to the second, it may be said that unfortunate management in some of the leading properties here, has had its demoralizing effects to a greater or less extent, in keeping out capital that would otherwise have invested.

There is one thing, however, certain, and that is, if this section has not given the showing that other mining camps of the Territory equally endowed have, it is not owing to any want of mineral resources. Marysville possesses every natural facility for a successful mining camp, but unfortunately her selection has not been for the best, during the past year or two, in getting parties at the head of affairs who would work for the best interests of the community.

We have a ten-stamp mill here, as good as new, but is at present lying idle, and as good as dead property to the owners.

There are some as fine properties here, as can be found in any mining camp in the Territory, and perhaps a greater variety of precious metals exist here than in any other section of the country.

Prominent among some of the most conspicuous mines at present is what is known as the Lucky Boy. This property is situated just above the Deer Trail and directly beneath the Plinto. The Lucky Boy has every condition in its favor for being another Horn Silver lode. It opens out first as a salinide of mercury lode, but as depth is attained the mercury seems to play out with the change of formation, and at the end of the present workings an incline of about 140 feet, run at an angle of 15° to 20°. The formation changes from what was originally a block chrysolite formation to that of the heaviest spar. The specific gravity of this spar must be exceedingly great, as it seems when hauled to be equal in weight to gold. Black sulphurets of silver are just beginning to come in this spar, and the probability is that within the next 10 or 15 feet run in on the spar, something in the way of gold and silver will be brought to light that will far eclipse the legends of the Arabian Nights; and this is no idle boast or exaggeration, but present indications give every inducement for that belief.

DEBTS.—In the Superior Court at Marysville, Monday, before Judge Keyser, in the debris suit of Yuba county vs. Eureka Lake & Canal Company Consolidated, the court fined the defendant \$250 for contempt of the injunction to cease discharging debris into Yuba river. The motion was on purely technical grounds. An injunction was issued and served when suit was commenced six months ago, but has been entirely disregarded by the defendant. There were four unsuccessful attempts to serve the order in regard to the contempt on defendant's agent, and service was finally made on defendant's attorneys. This is a new proceeding in the slickens suits.

A QUARTER of a million dollars' worth of bullion has been shipped from the Bonanza King mine, at Providence, San Bernardino county, from January 1st to the 1st of May—four months—all done with a ten-stamp crusher. For the month of April, a twenty-five days run, the bullion output was \$58,000, being the reduction of 568 tons of ore.

THE Greenville Bulletin of Plumas county Col., says: All the mining sharps in the county ridiculed Mills for sinking a shaft in American valley, but now that blue gravel has been struck and traces of gold found, the sharps begin to weaken and think that there may be some thing in geology and scientific mining, after all.

A CIRCULAR received from Battle Mountain announces that Frank Green of that place has concluded to erect smelting works there, and will smelt ores at \$20 per ton. He will pay railroad charges on ores, and customers will have the privilege of handling their own bullion, or he will dispose of it for them.

A SECOND payment of \$216,666 was made by English capitalists for the Drim Lummon mine of Montana, on the 18th of April, also 100,000 shares of the company's stock (on third of the whole) was also delivered to the seller, Thomas Cruse, who retains a large interest in the mine.

MECHANICAL PROGRESS.

Lubrication.

A subject which does not generally receive the attention it deserves was brought before the members of the Manchester Association of Employers, Foremen, and Draftsmen, at a recent Saturday meeting, in an interesting paper read by Mr. J. Veitch Wilson, on the lubrication of ordinary bearings and of bearings and faces subject to the action of steam. Mr. Wilson dealt with the question in an exhaustive manner. With regard to ordinary bearings under normal atmospheric conditions, he laid down that the lubricants to be employed should possess the following essential properties: They must not be inflammable under 350 degrees Fahr.; they must not act upon the metals with which they come in contact, nor oxidize, which would lead to spontaneous combustion and clogged machinery; they must have body adapted to the work to be done; their boiling-point must be sufficiently high to prevent evaporation and ensure durability, and their freezing point must be low enough to insure regularity of feed from oil cups and convenience in handling.

As the result of numerous experiments, he had become convinced that mineral oils were, used alone, unsatisfactory lubricants; but arising in mind the fact that mineral oils could be obtained in every respect as safe as the best animal oils, and that the admixture of mineral oil with animal or vegetable oils neutralized the acidity in the one case and the acidity and oxidizing tendency in the other, he was of opinion that the safest, most efficient, and most economical lubricants for all manner of bearings are to be found in a judicious mixture of animal, or vegetable, with good mineral oils.

With regard to cylinder lubricants, the peculiar conditions were the liberation of natural acids from vegetable and animal fats by the action of steam and heat, the action of these acids on the liners, and the evidence that in these acids are constituent parts of all animal and vegetable fats and oils; they could not be removed by process of refining. One of the lubricants largely in use was tallow, but that this was the cause of considerable injury to the engine cylinders he had abundant evidence to prove. From a mass of evidence he had collected upon the subject, he was convinced that, if care were exercised in the selection of the oil, and equal care in its preparation and application, hydrocarbon oil would be found thoroughly efficient as a cylinder lubricant, absolutely harmless and much more economical than tallow. Sometimes small percentage of vegetable or animal matter is added, in order to increase the lubricating properties, and in his experience this had always been attended with favorable results.

Hot air engines might be lubricated on the same principle as steam-cylinders, but gasolines presented a new and special feature, as their case the lubricant was not only subject temporarily to the intense heat of the explosion, but also came in direct contact with the flame, and was liable to be carbonized thereby. Therefore, vegetable or animal oils and fats were objectionable in steam cylinders, they were much more so in the cylinders of gas-engines.

TASKS AND BARRELS OF STEEL.—A Wolverhampton, Eng., firm have turned their attention to the manufacture of casks and barrels of steel. The two edges of the sheet steel which form the cask are brazed together in such a manner as to justify the title of "seamless," which the patentees have applied to these productions. The head of the barrel is also riveted to the body, so as to leave no seam, and the ends are shrunk on hot, thus making a very strong end, while, at the same time, the rims are strong enough to give a good purchase to the grapping hooks of hoists and cranes, for loading and unloading purposes. The bush for the tap does not project beyond the rim, so that the nozzle is not liable to be knocked out and injured. The casks are more durable than wood, less heavy and lighter—an eighteen gallon steel cask weighing some ten pounds less—a not unimportant consideration as regards transit. In point of shape, the steel barrel is exactly that of a formed wooden one, the bulge of the belly being of its being easily rolled along, and is managed by one man than drums can be two.

INSULATING WIRE.—A new method of insulating wire for electrical purposes has recently been patented by the Triplex Insulated Wire and Rubber Company. The method consists in tinning wire; it is covered with a layer of soft rubber, around which a strip of soaked linen is wrapped, and which in turn is covered by another layer of thick, hard rubber. For under-layers and wires another layer is added. The product of manufacture of this insulated wire is very simple, all the layers being put on in one operation by means of machinery, thus making it possible to furnish a comparatively cheap cable. The wire is fed from a reel into a groove upon two steel rollers heated with steam, simultaneously two strips of soft rubber, more than covering one-half of the wire, are pressed over the rubber. The coated wire is then automatically wrapped with soaked linen strips, and is carried to a second set of rollers, where two strips of hard rubber are pressed around it to a third coating.

A Reminiscence of Blacksmithing.

A correspondent of the *Blacksmith and Wheelwright* communicates to that journal the following reminiscence of blacksmithing in "ye olden time":

Forty years ago Northern Pennsylvania was almost a wilderness. My ancestors squatted on land from three to five miles apart from each other, and my father was for some time twenty miles away from any other blacksmith. The tools were of a very primitive kind. The bellows was made nearly square, and had a square box on top to hold wind, as they turned it. The drilling machine was a post-hole in the shop and a twelve-foot lever, with one or two of us boys on the other end, while my father, sitting down, did the drilling with a large iron bit and brace.

I have often seen him drill for two hours to do a job that can now be done by one of the new drill presses in fifteen minutes.

When he put on wagon tires he cut the tires in two pieces and then bent them with sledge hammers on a block made for that purpose. After being bent the two tires were riveted together and welded.

To make the tire the right size, it was laid on the wheel and the rim of the wheel was scratched with a "scratch awl." Rivets were put through the felloes at every joint. The screw-plate used then was a piece of steel three eighths thick and one and one-half inches wide, with three holes in it. The bolts had to be made to fit the plate. The first tap used by my father was made with a three square file. In those days bar iron was used for everything. The usual sizes sold by merchants were two inches by one-half, three-fourths or one inch. Horseshoes, small bolts, etc., were forged from this iron.

From September till March, we made shoes and nails until nine o'clock p. m. Now the smith can get shoes, nails, in short, everything, ready made; but forty years ago, it was very different. If my father were to see the tools I use now, he would ask me what they were for.

STEEL, STEAM, GAS AND WATER PIPE.—London *Iron* bears witness to the advantages of steel over iron in the making of pipe. It remarks that the Chameroy company make pipe of steel plate for conveying water under high pressure. The steel plates are coated with lead on both sides by immersion or otherwise, then rolled to form, riveted and soldered the whole length and covered with pitch. The first cost of steel is not much greater than that of iron, and the steel pipes possess considerable advantages over those of iron. The lead coating is superior on account of the fineness of grain in the steel; the resistance to tensile strain and internal pressure is 50 to 60 tons, and the resistance to deformation longitudinally from 30 to 40 times greater, while the superior elasticity of the steel plate permits of the pipes receiving tolerably hard knocks without being permanently deformed. For equal thickness the steel tubes stand twice the internal pressure of the iron, and being both light and strong, they are admirably adapted for laying down temporarily and taking up again.

LARGE GUN-BORING MACHINES.—Two exceptionally large gun-boring machines are now being constructed for the British government by a Manchester firm. The main bed for each machine weighs seventy-six tons; the main driving head-stocks, which are six feet high, with spindle weighing twenty-eight tons each, and the steady rests carrying the guns weigh twelve tons each. The bed for operating the boring bar is fifty-four feet long and weighs sixteen tons, and the total weight of each machine, when complete, will be 180 tons. The machines are constructed to bore six feet six inches diameter and fifty feet long, and the main head-stock is driven by a worm-wheel eight feet in diameter and four inches pitch. Two machines of similar construction were built for the government by the same firm a few years since, but the present ones are by far the largest of their kind yet constructed, and have been ordered to meet the requirements for heavier and more powerful ordnance.

A NOVELTY IN FIRE PROOF STRUCTURE.—A novel departure in the construction of fire-proof structures has been made by Mr. Samuel Liddle, of Hamilton, Nev., for which he has obtained a patent. The invention consists in a building with a hollow shell, and perforated iron posts and beams, which shell is to be filled with water from a reservoir above in case of fire. By an ingenious arrangement, the water is conducted through their hinges into the hollow blinds. After the fire the water may be drawn off into a tank, and pumped back into the reservoir again. This invention is also applicable to the hulls of vessels.

AMERICAN ENGINES IN LONDON.—In a plant they are now erecting over the river Thames, in London, England, they are sending two engines made by the Armington Sins Co., of Providence, R. I., for, after thoroughly experimenting, they could not find an engine made in England, or all Europe, that could do the work as well as the Yankee engine. Another engine is to be placed under the library of the House of Parliament; this was after a visit and a report of a committee, that the engine would run without noise or jar.

SCIENTIFIC PROGRESS.

The Visibility of Ruled Lines.

At a recent meeting of the Boston Scientific Society Prof. W. A. Rogers read a paper on line ruling, from which a few interesting points are worth special notice. The Professor stated that he had ruled band lines, in which the lines were so fine and delicate that they could not be distinguished with a microscope, although their spacing was much within the power of the microscope to resolve. Yet there could be no mistake about the existence of the lines, for several reasons: The pressure of the diamond on the glass was sufficient to produce the cut; while moving over the surface of the glass it produced the peculiar singing sound, which is always indicative of the action of the diamond on glass, and finally the lines became visible when filled with fine graphite.

There is a limit beyond which lines cannot be filled with graphite. That limit is from one eighth to one nine thousandth of an inch.

A most surprising result of some of the experiments of Prof. Rogers is that the naked eye can discern not only single lines, that cannot be seen with a microscope, but that it can also detect errors which the microscope will not show.

Thus, he has a glass upon which lines are distinctly visible to the naked eye, and, although an objective of low power will show them, one of a higher will not.

Again, even errors or imperfections in ruling, which cannot be seen or measured with the microscope, may reveal themselves to the eye by a peculiar waviness of the image.

The Professor attributes the failure of the objective to show the lines, as mentioned above, to the present impossibility of illuminating the lines with light of the exact angle of incidence required, and the proper angle of illumination, he thinks, deserves more careful attention.

THE VOLATILIZATION OF SOLIDS.—In a communication to the Manchester Literary and Philosophical Society, Mr. Henry Wilde deals briefly with the behavior of solids at high temperatures, in relation to the property possessed by these solids of giving off vapor of their own substance. In connection with incandescent electric lamps this phenomenon is made susceptible of easy study. Platinum threads were at first used for these lamps; but it was soon found that an atmosphere of platinum vapor was formed in the interior of the bulb, which, after the lamp had been in action a considerable number of hours, condensed on the surface of the glass, and formed a bright reflecting surface like a mirror. The substitution of a filament of carbon for the platinum in lamps of this order overcame the objection to a great extent; for the vaporization and condensation of the incandescent material, however interesting from a philosophical standpoint, was fraught with much practical inconvenience. Still, when a high degree of incandescence is imparted to the carbon in the modern lamp, an atmosphere of its vapor is formed in the interior of the bulb, which condenses on the glass, forming a dark lustrous surface, and thereby obstructing the light in the same manner as when a filament of platinum was employed. Thus the behavior of the carbon and platinum in such cases clearly shows that the most dense and refractory substances in nature vaporize at high temperatures while still retaining their solid form. Electric lamps were shown by Mr. Wilde, exhibiting the condensed platinum and carbon on the interior surfaces of the glass bulbs.

PUTTING PELAGIC ANIMALS TO SLEEP.—The *American Naturalist* says Dr. Fol, of Geneva, has made the important discovery that eel-eaters and eel-binders may be rendered insensible and kept so for hours and even days, without injury, by saturating the water with carbonic acid. The containing vessel must, of course, be hermetically closed. The animal at once becomes insensible and motionless, but preserves its natural appearance, and recovers at once when again placed in pure sea water. This method may be used not only for obtaining lifelike photographs, but also, as Dr. Fol suggests, for transporting animals alive. Fishes and mollusks do not survive this treatment, and crustaceans for only a short time.

Dr. Fol tried various narcotics, but found that small doses would not bring the animals to rest, while large doses acted as poisons. The same proved true of tobacco smoke and aqueous solutions of ether, chloroform, and ethyl bromide. Sulphuric acid and carbonic oxide gave satisfactory results in only a few cases.

AN INSECT EXHIBITION is to be held in Paris this year, from July 1st, for just three weeks, under the auspices of the Central Society of Agriculture and Insectology. It will include first, useful insects; second, their products, raw, and in the first transformations; third, apparatus and instruments used in the preparation of those products; fourth, injurious insects and the various processes of destroying them; fifth, everything relating to insectology.

MOUNT ETNA is in eruption, pouring out from the central crater a stream of lava. Vesuvius is in its usual passive state, although there is always a subterranean stream of lava flowing. Visitors are conducted by guides to the spot where the liquid fire may be seen through an aperture in the solid crust of lava. The column of smoke constantly ascends, and at intervals at night there is a brilliant light,

West Indian Phosphate.

The works at Mona Island, West Indies, which were started about two years ago, are now well advanced, and with a full productive capacity of from 20,000 to 30,000 tons per year.

The guano is already in high favor in the United States, where it has been thoroughly tested, and is pronounced one of the best, if not the very best, of such materials imported there.

The phosphate rock, of which now considerable is raised, is in active request in England and on the Continent, especially the latter, where the more highly concentrated fertilizers are generally used.

The deposits or accumulations occur on the floors of the immense caves penetrating the coast line of the island—a tertiary coral rock—for ten or twelve miles almost interruptedly.

The thickness of the deposits is usually about four or five feet. The rock phosphate, which is really phosphatized coral rock, is found both as a massive stratum or shell underlying the bed guano, and also incrusting the masses of rock found imbedded in the guano. The deposits are very interesting from a scientific point of view. The crystallized calcite, aragonite, and gypsum are found as pure as if from a primary formation.

Many new combinations of phosphoric acid, giving rise to a new series of phosphatic minerals, are quite abundant. The two examined and described by Professor Sheppard, of New Haven, as monite and monitite are bi-basic and hold the highest combination of phosphoric acid known in any natural phosphate. They occur well crystallized. The Mona guano analyzes fifty-two to sixty-eight per cent bone phosphate on a dry basis, and commercial samples of the rock eighty-seven to eighty-eight per cent bone phosphate. Both are singularly free from iron and alumina. Many Indian relics and remains have been found in and under deposits, viz.: implements, pottery, shells, bones, etc. Some of these most interesting relics are in my possession. The work is under the personal supervision of Mr. J. G. Miller, of Ottawa, a practical scientist. —*American Railroad Journal*.

AN EBONITE THERMOMETER.—A thermometer more sensitive than the mercurial indicator—one that will indicate the thousandth part of a degree centigrade is promised by M. Michelson, who has demonstrated the principle on which his very sensitive instrument is constructed before the French Physical Society. He does not employ mercury or spirits for his thermometer, but something that expands still more in the presence of heat—namely, hardened rubber or ebonite. The instrument is in the form of a spring, which is made of platinum on one side and ebonite on the other, and as the latter dilates some ten times more than the former under heat, there is naturally exerted a rise and fall in force everytime a rise and fall of temperature takes place. The force exerted is communicated to a delicate lever or arm, and this, reflecting a beam of light from a lamp, magnifies the force that has been developed, and renders the change easily readable to the eye. Edison, it may be remembered, employed rubber for a similar purpose. —*Cotton, Wool and Iron*.

PRODUCTION OF SULPHUR IN THE SOIL OF PARIS.—Some recent excavations for public works, in Paris, have opened masses of mixed rubbish in which there is an abundance of native sulphur. Its crystallization can be perceived by the naked eye, and the microscope shows that the crystals are octahedral, with the usual forms of natural crystals, sometimes truncated and combined with right prisms. Danbree attributes the origin of the sulphur to the simultaneous presence of sulphate of lime and organic matters which are associated with it, such as vegetable remains, manure, leather, and fragments of bones. In some places, the quantity of sulphur is sufficient to pay for mining. It consists of a breccia of small fragments, incrustated with crystalline sulphur, which helps to cement them together. Crystallized sulphur is also produced between fibers of decayed wood. When the bed was opened it exhaled a powerful odor, resembling that of phosphorus, which was attributed to phosphuretted hydrogen. —*Comptes Rendus*.

DUST, MIST, AND CLOUDS.—Mr. Aitken draws the following conclusions from an extensive series of experiments: "Whenever vapor condenses in the atmosphere, the condensation is always made on a solid nucleus, which is furnished by particles of dust. Without dust there would be neither mists nor clouds, and the super-saturated air would transform every object upon the earth's surface into a condenser upon which it would deposit its excess of water. Whenever the breath becomes visible in a cold atmosphere it demonstrates the impure and dusty condition of the air. The foam of the sea, meteoric matter, and fires are fertile sources of the dust and impurity." —*Les Mondes*.

BRONZE COLORS can be fixed upon glass or porcelain, according to Professor Boettger, by painting the articles with a concentrated solution of potash water glass of thirty degrees B. and dusting them with the bronze powder. The latter adheres so firmly that it will not be affected by water, and may be polished with steel or agate.

WORK on the Northern Pacific Railroad bridge across the Willamette was commenced by driving piles. It is publicly stated that parties owning dock property above the site of the bridge will immediately begin an injunction suit. The bridge will be built in conformity with the views of United States engineers, and the draw spans will be 175 feet in clear.

THE revenue cutter, *Thomas Corwin*, that since her return from her famous cruise, the middle of last November, has been lying in this port, is about to leave for the Arctic on her regular six months' cruise.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Alpine.

RICH STRIKE IN THE POLARIS.—Monitor *Argus*, May 18: A very favorable strike was made last Tuesday in what is known as the Polaris location, virtually a continuation or location between the Stella and Colorado No. 2 mines. T. N. Hansen, one of the owners, brought into town the same day some samples of ore and had an assay, which showed \$86.73 silver per ton, with a trace of gold. He reports that this find was made within a distance of fifteen feet from the surface, and the entire length of the tunnel does not exceed twelve feet, and reports that an ore body has been encountered that had every indication of proving permanent and rich. We congratulate Messrs. T. N. Hansen and D. R. Hawkins, the owners of this claim, on striking such good ore so near the surface.

Amador.

VOLCANIC MINING ITEMS.—Amador *Dispatch*, May 16: A very promising gold quartz mine has been recently developed by Mr. Canvin near Volcano. Mr. Hadler, near the old Markley, sank a shaft 100 ft. deep on a vein that in earlier days yielded excellent results. All the new ground in lower portion of shaft, shows high grade ore some two feet broad. The owner is seeking for assistance to plant larger machinery than heretofore used, for the purpose of sinking 100 ft. deeper. The twenty stamps of the Downs mill are now running steadily. The stopes between the 400 ft. and 500 ft. levels are supplying the mill with ore of apparently inexhaustible qualities. Productive as usual. It is reported that a gravel mine near North fork, on the Mokelumne river, was sold a few days ago to San Francisco parties. Work in the deepest shaft (320 ft.) of the Aene mine, some three miles above Volcano, was stopped last Thursday. Since last November the mine has been under the satisfactory management of Mr. Stetson, an old quartz miner identified with the mining interests of Calaveras and Amador for years. The heavy flow of water encountered in the 300 ft. level, is stated to be the principal cause of deferring operations there for the present. The Company paid all demands promptly and continues working a few men near the surface. Mr. Muck is developing large quantities of ore on the former Sorocco mine. The Volcano Tunnel Co. are now realizing expectations of dividends, under the prosperous supervision of Supt. Doolittle, a practical hydraulic miner. Although the grade of the large flume in tunnel is sufficient and the requisite supply of water has been very limited, a large space of ground has been swept off to the flume grade. The clean-up will be large. The gravel remaining below the flume grade is all new, rich, and estimated to be from twenty to fifty feet in depth. It is intended to hoist this gravel into the flume during the summer, sufficient water being in command then for that purpose.

LAMING GRAVEL CLAIM.—Amador *Ledger*, May 16: A large force of men are employed upon this gravel mine, situated in the neighborhood of Irish hill, in lone valley, consisting of 15 white men, and a lot of Chinamen, the latter under the direction of Hugh Clark, formerly underground foreman of the lone coal mine. The pay dirt is very rich, as much as \$7.50 to the pan has been taken out. The gravel is from four to six feet thick, the richest portion resting on the bedrock. This gravel, however, lies under from 20 to 25 ft. of top-dirt which has to be serped off before the gold can be got at. One pit, about 25 ft. square, has been worked out, and yielded \$1900. Another pit is now almost ready to commence mining out. Although so very rich the enormous expense involved in removing the top-dirt renders it problematical whether it can be worked profitably. The nature of the ground—a sort of quicksand in places—makes it hazardous to attempt extracting the pay-dirt by drifting.

MANMOTH.—There is little going on at this mine. The mill is still idle. Only two men are employed stopping rock. The tunnel is being pushed ahead as vigorously as possible. It is doubtful whether the mill will be started again until existing litigation has been settled. The wet weather of the past week has made it impracticable to haul ore even the short distance from the mine to the mill.

MISCELLANEOUS.—The Kelly mine is at a standstill, the boggy state of the roads making it impossible to haul ore from the Morgan mine.

SUTTER CREEK.—Developments at the Mahoney are looking favorable. A force of men have been working at the 900 level for three weeks past. A crosscut at this depth has been run west, and in the last few days a change has taken place in the nature of the ground. Gangue and slate has put in an appearance, which is considered a good indication. Some quartz has been met with, which prospects fairly. At the mill 20 stamps are kept running steadily on rock from the open cut near the mill, and seems to be paying. Twenty stamps of the Amador Consolidated are kept going on ore taken from an open cut on the property. The quartz now being taken out is of better quality than at anytime before.

Calaveras.

STARTED AGAIN.—Calaveras *Chronicle*, May 17: The Empire mine, in Old Woman's gulch, started up again this week. We are informed that the mine, which is worked through an incline tunnel something like 600 ft. in length, has been cleared of the water, and active operations commenced. The mill was started and everything runs smoothly and satisfactorily.

ROBBERED.—Some thieves recently robbed the sluice boxes in the claim of W. V. Clark, near Railroad flat. The five first boxes were cleaned up and contents appropriated by the wretches. A night watchman had been employed to guard the claim against the thieves for some time, but on the night in question there was no guard, a fact upon which the thieves seemed to be well posted. Mr. Clark was exceedingly unfortunate thus to lose the fruits of a whole season's run. From what was left by the thieves, together with what was cleaned up in the daytime previous to the robbery, Mr. Clark realized about 50 cents a day for his labor during the season.

MURPHYS.—Calaveras *Citizen*, May 17: Business is booming now in the vicinity of Murphys. Know-

lton, Dodge and Sublet are putting up a Kei quartz mill on the O. K. and Buckhorn mines, near the Sperry spring, of five tons daily capacity. Stephen Kendall is the millwright. The Fair has paid off, and Tom Goodwin, the superintendent of the Calaveras mine, is stirring up the boys. Oro Plata is running night and day with a force of men and taking out good pay.

El Dorado.

THE DELMARCA MINE.—Mt. Democrat, May 18: This mine has developed into one of the most promising quartz mines in the county. It is located about one mile and a half northeast of Kelsey, one of the large reservoirs of the California Water and Mining Co. One of the shafts, at a depth of 90 ft., developed a ledge six ft. wide that averages 90 ft. in consequence of a surplus of water shaft was abandoned, and another was started at a distance to the southeastward, which "paid for ground down." This was on a supposed "see but it gradually developed with depth into a four ledge, bearing rich sulphurets in vast quantities 90-pound lot of the ore was worked, and yielded 30c at the rate of about \$180 per ton. A roasting mill and substantial hoisting works are to be erected during the summer, when work will be vigorously prosecuted. The present owners, Messrs. McG Kelley, are residents of Kelsey.

PEKIN MINING DISTRICT.—A largely-attended meeting of miners was held at the residence of J. son and son, China Hill, Mud Springs township (Wednesday May 10th, for the purpose of electing new Recorder for Pekin Mining district, the former Recorder having removed from the district, in view of a great number of new discoveries have recently made, and in which there has been a great revival of the mining industry. By unanimous choice the vacant office was conferred upon J. W. John, who with his father has been among the most successful miners of the district, and largely instrumental in developing its capabilities and attracting attention to it. The most notable feature of this district is its great "greenstone belt," along which are now a score or more of richly paying mining enterprises in course of vigorous prosecution and development. There is every indication that this district will warmly contest with Grizzly Flat for distinction of being recognized as the best mining camp in El Dorado county, and Grizzly will have look sharply to her laurels.

Mariposa.

DILTZ MINE.—Mariposa *Gazette*, May 18: The return of Captain Diltz from the East, work on this mine has been resumed by a force of men, they are blasting away a heavy bank of ledge lined with strata of quartz, which is piled for mining purposes, and the dirt run out on a car washed through the sluices. The mine at this point looks exceedingly well, and the further prospect of the work will no doubt soon develop a rich deposit of gold—particularly characteristic of this mines besides a large quantity of good milling ore, will be preserved for future operations. The old tunnel has fallen in, and cannot be made available for use at present. Captain Diltz recently visited Whitlock mines, and found them almost inaccessible to reach, caused by the overgrowth of chaparral and chinquapin. The Captain immediately employed men to clear away the thicket of brush, making mines accessible to visitors. The Spencer shows a vein from three to nine feet thick and good looking ore. The Whitlock shows a vein six feet in thickness, at a point where the ore runs 20 to 25 tons when last worked. There are also places on this vein which look remarkably good. The Schroeder mine is said to be making good of the water from the upper ditch supplied by late rains. Large quantities of surface dirt is washed away from the mine and vein.

Mono.

GORILLA.—Homer *Index*, May 19: Working is pushed in all three of the adits penetrating the Gorilla lode, and the ore bodies are everywhere strong and of good quality. Recently work commenced on three seams of ore crossing the lode at right angles, and a few feet into the hill these seams came together, forming a foot solid vein of high-grade ore.

ILLINOIS.—Callahan and Isbell are opening one of the most promising properties in this part of the county, on the mountain side overlooking western shore of Mono Lake.

MAY LUNDY.—This mine is making regular very heavy shipments of bullion, though we are yet at liberty to give the figures. The mine is in excellent condition and is turning out some very fine ore, in the extraction of which about sixty men are employed underground. The road is improving, everything about the mill is running smoothly.

IN BRIEF.—The Virginia Creek Hydraulic Mining Company, operating on a large gravel field adjacent to the Old Mono diggings, is now employing a large force of men, and meeting with every encouragement. The Mono Lake Hydraulic Mining Company is working the usual force, though the extreme cold weather has somewhat retarded the progress of late. McKinnon and McDonald are opening their Ohio mine, near Mt. Gibbs, and struck rich silver ore equal to that of the Ella Bay. Considerable prospecting is being carried on in the south end of Tioga district, and with the most encouraging results. The Grizzly mine, above Mono Lake, is still improving in appearance as the tunnel progresses. Work is soon to be commenced on several mining locations near the head of Mill Creek canyon. Jordan district and the Mono diggings are beginning to show considerable life.

Nevada.

NOTES.—Nevada *Transcript*, May 19: The Banner Con Tunnel Co. (Ternan & Co.), at the hill, a short distance from this city, will in a few days have its 10-stamp quartz mill running. But people have any idea of the amount of prospect that is going on within a mile or two from the city. Go in any direction, and prospectors will be found doing all kinds of work in developing lodes. There is one vast net-work of valuable ledges in the vicinity, and it would seem, judging from the new enterprises that are being started, that the newness men are just beginning to find it out. A few years ago if any one, except a capitalist, commenced operations on such a thing as a quartz ledge, his credit went down par with a rush, and every state of affairs has all subsided now, and every one can afford it is taking an interest in quartz.

in this neighborhood, and the entire price spent in this city. That is one reason why this city is so prosperous, and its quartz interest is up so finely.

Plumas.

QUONSI HILL.—*Plumas National*, May 12: It is on good authority that the tunnel at Quonisi is now in good pay gravel, and is found right for the bedrock. The "pay-grit" is three feet deep, a beautiful dark blue gravel, gold in good paying prospects. No flume is to be had there at present, and the prospect is to be done with the old-fashioned "dredge" but that slow-going method will give a fair what the gravel is worth, and the necessary payments will be made as soon as possible. The quartz of Quonisi hill is pretty well assured, and no doubt but that in a year or two from this will rival the far-famed Bald Mountain, of Butte.

OLDWOODS.—Mr. Parsons has the machinery at the Deadwood found and has the tunnel up. The shaft is found to be in good ground, the timbers being solid. A few days more will be required to get everything to run and then we shall expect to hear of some results.

QUARTZ.—Mr. Geo. Lee brought in some specimens from the Piazoumi mine, near Dutch Lake. The quartz shows free gold in abundance, ranging from four to 15 ft wide, all promising. It is pretty well opened and developed, one being run on it which is 500 ft long. The Piazoumi mine, has expended several thousands in opening it up, and now finds himself helped to put up machinery. This is a good omen for a capitalist.

GREENVILLE MOUNTAIN.—*Greenville Bulletin*, May 17: The ledge was struck the tunnel was continued 40 ft beyond it in order to make certain of the ore body sought, and not a mere prospect.

The result having been found satisfactory, has then started along on the hanging wall of this, is now in about 130 ft. Where the ledge was struck, it was found of the same width as the old workings, 400 ft above; as the ore did not prospect worth much, this reason the drift was continued alongside of the ledge; the latter being soft and required heavy timbering all the way, the hanging wall the ground is solid and no timber is needed. At short intervals apart as the ledge is cut into and the ore found; a very confident assurance that a body of ore will be cut into about 200 ft ahead of the face of the drift. Should any good ore be in the main time, of course it will be got by back when the ledge shall be opened for.

The present condition and future prospects of Greenville Mountain mine are now very encouraging all who have interests in the district.

DEPT. MINE.—The work of putting down the greater depth has been hindered during the weeks by continuance of rainy weather; in addition additional pumping facilities have been the shaft is again clear of water, and sinking resumed. Up to this time but eight have been kept running. Mr. Davis says about of the present week he will drop eight more time to run to till it shall be seen what future results may be made in the mine; his confidence greater than ever that the future will far surpass anything yet seen in the Greenville.

Shasta.

MINE.—*Shasta Courier*, May 10: The mine above the Tower House, in French Creek, is a fine paying property. Inside of Mr. Shaffer has cleaned up over \$30,000 quartz crushed in a small amara. The work of opening the mine, is not near complete but the ore grows better as the work progresses, and it is noted that there is already fully as much ore as has been crushed. If expectations are realized the mine will be tapped soon by tunnel that will be mine to be not only one of the extraordinary richness but of mammoth extent. Shaffer was in the hotel business and pitched in to at mine in earnest, and we heard a mining man remark a few weeks ago that "if the owner government patent for the mine he would get for it that would make his eyes stick out."

NEVADA.

Washoe District.

ELK CON.—*Enterprise*, May 16:—The joint Nevada mine on the 2900 level is down about it will eventually be sunk to the 3000 level to with the drift now going north in the Mexican ledge. Some ore is being taken out from drift No. 2 on the 2900 level, but they are near of the deposit in that direction.

ELK CON.—North drift No. 2 on the 2900 level has now reached the terminus of the ore in section.

ELK CON.—The work for the connection of the winze down from the 2400 level is progressing well. A new winze has been started near of the south drift, which will follow the ore. It will go down at an angle of about 55 degrees.

ELK CON.—Not much work has been done on the 2900 level, but the material in the drifts is very little change.

LOW JACKET.—The mine is looking well and well. Not only is there being found much ore in the old stopes, but also considerable amount that is productive is being opened.

ELK CON.—The northwest drift on the 2400 level is being advanced in ground that is hard. The diamond drill shows that this characteristic will continue for a considerable distance.

ELK CON.—The C and C winze is making progress. Drain boxes are being put in on the 2900 level, and on the 2900 level the usual proceeding made in the main south drift.

ELK CON.—The old Central tunnel is being repaired and is also being made to the ladders in the mine. Some ore is still being extracted from the drifts.

ELK CON.—In crosscut No. 3 on the 2600 level progress has been made during the week in

quartz of a good appearance, though not carrying much metal.

AXMINSTER.—Some fair ore is being extracted from the west drift. In other directions there are favorable indications.

CROWN POINT.—The usual amount of ore is being extracted and sent to the mills.

Columbus District.

NORTHERN BELLE.—*True Exposure*, May 19: A large amount of prospecting is being done, and it is being pushed ahead as speedily as possible. The stopes from the fourth shaft level look promising and continue their usual yield of ore. The ore has improved somewhat, both in extent and quality, above the first shaft level. The section of the mine above the adit level looks about the same as at the date of the last report. Some very good ore is being extracted from the seventh level, the outlook at that point being quite promising. One of a very fair grade is being encountered in the stopes at the eastern end of the ninth level. It improves in appearance as the work progresses. The daily output of ore has been about 65 tons, which is sent to the mill. Both of the mills are running as usual, and doing good work. The bullion shipments amounted to \$13,831.58 for the week ending May 17th, and aggregate \$27,413.80 on May account to the same date.

MOUNT DIABLO.—The stopes from winze No. 2 shows two feet of 505 ore. The ledge below this stopes is about 10 inches wide, and gives assays of ore worth \$60 per ton. The stopes above the third level, near the head of winze No. 2, is showing a foot of 570 ore. The stopes near winze No. 4 is yielding a small amount of \$100 chloride, while the intermediate stopes above winze No. 1, between the second and third levels, is giving a little \$150 ore from a narrow ledge. The east intermediate, between the first and second levels, is turning out considerable 570 ore. The stopes from the west drift from the Callison winze shows some two feet of 570 ore, the formation in the extreme western end of the stopes shows improvement as the work progresses. A little ore of a good grade is being stoped from a point near the shaft on the first level. A bullion shipment amounting to \$5,676.51 was made on the 10th instant, and another of \$7,550.58 on the 14th.

Eureka District.

EUREKA TUNNEL.—*Eureka Sentinel*, May 16: There are fifty-two men on the pay roll at the Eureka Tunnel, of whom only eight are working on ore, the remaining forty-four being engaged in dead work. Still the mine is paying expenses right along and laying aside a surplus every week for the reduction of the company's debt. Within the next week or ten days, the mass of dead work now being done, handling ore seven or eight times, and all that, will be over with. The cribbing in the new shaft, which is now down to the depth required to relieve the first level, was finished last night. Work on the station will be commenced to-day and pushed forward as rapidly as possible. After that the apparatus will be put in for working the cage without delay. The building up of ore by steam, will mark an important era in the history of the Eureka Tunnel. The output of ore will be greatly enlarged at once, and running expenses greatly curtailed. The shaft will be sunk deeper continuously to connect with the workings on the second level. The ambition of Gen. Connor is to have all ore come up as soon as practicable by steam through the new shaft. When this is realized, if developments keep pace with the outlook at several points, the tunnel will cease to be called a "small mine" and will have to be classed among the mines called big. The Addison chamber, in which the principal mining is being done at present, looks better from day to day and improves always the deeper it is explored.

Garfield District.

WESTERN.—*Virginia Enterprise*, May 18: The Western mine, at Garfield, is shipping ore to the Northern Belle mill at Belleville. During the last month 123 tons were shipped there, yielding \$226 per ton, and 15 tons were shipped to San Francisco that yielded \$602 per ton.

Mount Cory District.

MILL AND FURNACE.—*Hawthorne Bulletin*, May 18: Constructing engineers, who will immediately begin the work of surveying and grading the mill and furnace for the Mount Cory M. Co., are expected here in a few days. The plans and specifications are nearly finished, and the engineers will leave San Francisco as soon as all are completed. It is authoritatively stated that the capacity of the mill will not be less than 20 stamps. The location has not yet been decided upon.

Pinto District.

ORE.—*Eureka Sentinel*, May 18: Some high-grade ore is coming out of the Queen mine. This property is a constant ore producer. Messrs. Berryman Bros. are still taking ore out of the Silver Nugget mine, Silverado mountain. Several new locations of mining claims have been made lately in Pinto mining district, which is fast coming into favor with prospectors. The old Champion mine, on Alhambra hill, has been twice relocated, and will be worked by O. H. Smith and Richard Berryman. A tunnel will be started and run on the contact of the limestone and trachyte, from which a crosscut will be driven in under the old workings upon the ledge. There is some good ore in sight.

Secret Canyon District.

MONITOR.—The main tunnel of the Monitor mine is in 100 ft. The indications are very good at the face, but it will be carried forward 150 ft further, from which point an upraise will be made to connect with a shaft sunk to a depth of 12 ft upon the ledge. The ore from this mine is of excellent quality, and the ledge is strong and appears permanent. There is considerable quartz ore, containing black metal and bright chloride of silver, coming out of the Metaline mine, Secret Canyon district. The ore is taken from a seam which makes between limestone and trachyte. There are veins of almost pure magnesite in the mine, which, when broken into lumps, can be used as chalk, making a clear, white mark.

Tuscarora District.

ELKO CON.—*Times-Review*, May 17: During the past week drift No. 3 has been advanced a distance of five feet; total length, 100 ft. Owing to foul air have been obliged to discontinue operations in this drift. The ledge is in fine quality of quartz. Drift No. 4 has been extended a distance of 15 ft; total length, 157 ft. During the past few feet the ledge has produced quartz containing large quantities of sulphurets. During the next week expect to make

connection with shaft No. 1, which will give a sufficient supply of good air for all purposes. As soon as connection is made work will be resumed at all points of the mine.

NORTH BELLE ISLE.—Winze from the 150 level has been opened up and is being put in shape to resume sinking, and will be connected with the 300 level. Present depth, 40 ft.

ARGENTA.—No. 2 upraise above 700 level is up 43 ft. East drift from winze in 23 ft. The ore now being stoped is good and the stopes are looking well. The mill will be ready to start up on the 24th inst.

ARIZONA.

NOTES.—*Prescott Courier*, May 15: The best news we have to relate, this morning, is that large hoisting works, an air compressor and other machinery, for the Peck mine, will arrive shortly. Sinking below the first water level will then commence. L. D. Hardy, one of the best mill men on the Pacific Coast, is at the mine. We heard that the 11 tons of selected ore from the Occident mine (property of the Peck Co.), worked about \$1,800 per ton in San Francisco. All who have examined the Howell Co's Belle mine pronounce it a fine property. It is producing immense quantities of ore. Miners say that Hatz & Majia have a very rich mine in Hassiyampa creek. Slabs of the ore seen by us in this town were rich. The Dosoris and Silver Belt mines continue to produce abundance of rich silver ore. Mine owners who have plenty of rich rock are hoping that some man or company will come in and start other reduction works.

MINING IN YUMA COUNTY.—*Arizona Sentinel*, May 19: Five mines in the Hacuar mountains in this county, have been sold for \$100,000. The mines are about nine miles north of Chien's wells, and seven miles west of old Campo Seco. The ores are copper, carrying gold and silver. Copper mining in Yuma county has never been thoroughly tried, and from the character and quantity of the ores of this district, it will surely prove a success. The Hacuar country will greatly help the trade of the northern portion of Yuma county, and will in a few months make heavy shipments of copper bullion. The copper industry will have another impetus through the development of promising claims near William's Fork, owned by prominent citizens of Los Angeles. There is also considerable activity in the mines around Plomosa, by which summing up, the opening of the Hacuar country, William's Fork and Plomosa, will soon cause the streets of Ehrenberg to bustle with life and activity. Farther south, Silver district is flourishing with a magnificent 40-ton smelter and a quartz mill in active and successful operation, both producing silver bullion in paying quantities. Castle Dome is looking up, and so are the splendid mines in the Mohawk mountains. The ores from the latter place are of a promising character of quartz carrying gold and silver in both a chloride and sulphuretted form. A general resume of the mining outlook of this county can be stated in a few words: That to-day the mines of this county show as good prospects as any in the Territory, and that the majority of the mining prospects now being worked are paying their owners handsome and solid profits.

COLORADO.

ATLANTIC DISTRICT.—*Colorado Miner*, May 12: Our reporter paid a visit to the mines of Atlantic district this week. The Empire and Middle Park wagon road was found free from snow and in good condition for wagons up to a point on the big bend where the trail leaves the road. The first property visited was the Edith Belle lode, discovered in 1881 by S. H. Bennett and Mr. Stanton. This mine has lain quiet for some time though it is intended to prosecute work diligently the coming season. It is located on Russell mountain about a quarter of a mile from the Middle Park road, and is reached by a trail of slight grade, which could be converted to a good wagon road at comparatively slight expense. A good frame house, capable of accommodating 12 men, has been erected, together with a log shaft-house and blacksmith shop. The developments consist of a discovery shaft 20 ft deep, a crosscut 25 ft in length, and several open cuts. A cut was run this spring which has just entered cover, exposing a vein of quartz of two to six inches in width, carrying finely disseminated mineral, specimens assaying from \$329 to \$436 per ton and carrying one ounce in gold. Some of the specimens, which showed no mineral, after being placed in the furnace were covered with buttons of silver "roasted" out.

A. AND P. TUNNEL.—The tunnel is now in 1450 ft and going a head from two to three ft a day. The rock for 100 ft has been unusually hard. Before that a spur was driven on some 200 ft, which, however, circled in and out of the line of the tunnel like a wave. It contained soft gangue and some mineral that ran as high as 47 ounces silver. Fifteen men are employed, and the heading is supposed to be within 50 to 60 ft of the Diamond Joe. The Potosi lode was struck some 500 ft in. Upon this Messrs. Snow and Riggs have drifted under lease 175 ft westerly, having a depth at the breast of over 600 ft. The crevice has specks of mineral and looks more promising than heretofore.

IDAHO.

VIENNA NEWS.—*Ketchum Keystone*, May 14: Reliable persons from the upper country inform us that operations in Vienna will assume a lively shape at an early date. The immense quartz mill of the Vienna Co. is standing ready for a long run with huge amounts of ore from the Mountain King, Solace and Vienna mines. The only thing now causing delay is the snow, which, owing to the cold weather experienced in April, has been a month later in melting than was experienced in March. Capt. Henry Guyer, who, it will be remembered, was engaged to run the Vienna Co.'s works just as soon as the season would permit, in '83, is on his way to Vienna, and other signs of opening operations begin to show as snow leaves the Sawtooth divide.

MONTANA.

THE GRANITE MOUNTAIN.—*Inter-Mountain*, May 14: The Granite Mountain mine, in the Phillipsburg district, now ranks as one of the richest silver mines in the Territory. The vein is rich, regular and permanent, and the ore dump is rapidly assuming mammoth proportions. It is the intention of the company, in the near future, to erect

a mill, but in the meantime a considerable amount of No. 1 ore will be shipped to St. Louis for reduction. A contract has just been signed for the transportation of 1,000 tons of \$500 rock to the railroad, and it is now being sacked for shipment. One of the owners of the property was approached this morning by a reporter and asked why he did not have the ore milled in Butte, and the reply was that it is cheaper to ship it to St. Louis. It could be very easily milled in Butte, as it is an ordinary sulphuret ore containing some ruby and antimonial silver. The Butte mills, however, have all the home ore they can work, and it is for this reason, perhaps, that arrangements for the treatment here of the Granite Mountain product could not be made.

IMPROVEMENTS AT THE SMELTER.—*Butte Miner*, May 16: Under the energetic management of Supt. W. J. King the Bell works are rapidly getting into shape for the extensive operations, which will be commenced whenever the new shaft is connected with the old workings and ore can be hoisted in sufficient quantity to supply both blasts at the smelter. Among other important improvements which will greatly facilitate the handling of ore, is a tramway running under the calcining furnace, connecting with an elevator and elevated tramway, by which the cars can be filled with ore from the furnaces and transported direct to the blast feeds. The calcining furnaces have been doing some extraordinary work during the past week, each furnace averaging 10½ tons of ore per day, which was calcined down to less than five per cent sulphur. Twenty-one tons of ore is run through the single blast each day, which produces a daily matte output of about 10 tons. At the mine, work on the new three-compartment shaft is steadily progressing. The work of putting in the station set at the 270 was finished last Friday, and crosscutting to the old workings may now be commenced at any time, but the intention is to drive work on the shaft as rapidly as possible to the 400 and crosscut to a point beneath the old workings, with which connection will be made by an upraise. It is expected that this connection will be made within the next 30 days, when stoping will be commenced on the high-grade west vein, and from 40 to 60 tons per day hoisted to supply both blasts of the smelter, the output of which will then be increased to from 20 to 30 tons of matte per day.

NEW MEXICO.

THE CARLISLE MINE.—*New Southwest*, May 14: A gentleman just in from the Carlisle mine at Steele Rock, informs us the Carlisle Co. is still working away with a large force of men. The principal working is in the 6x8 ft shaft. The company intend sinking this shaft to a depth of 340 ft before running the level. It is down already quite a distance. He says they were preparing to start up 15 stamps of the mill as he left. He also informed us that the mine will, in all probability, develop into one of the greatest mines on the continent. The ore bodies on the surface, and exposed by the working is simply enormous. It is a sulphuret ore and when down to water level it becomes base, but the machinery of the company under the skillful management of Wm. Farish the superintendent, is such, and has been so constructed that the treatment of it is provided for. It seems to be the opinion of every mining man who has seen this property, that there is nothing anywhere that exceeds it. The croppings are immense, and the vein is as well defined as the hills through which it passes. The Star of the West adjoining this claim on the west, the Center and Pennsylvania adjoining it on the east and all on the same lode, promise to develop into big mines also. The latter claims are owned by different parties. But as yet little work has been done on them. These mines are in Grant county and in the Steele Rock mining district. There are a great many fine prospects out there. Indeed we know of no mining camp anywhere in any county that has a more encouraging outlook than this district. It is beautifully located, only 15 miles from Richmond and the Gila river, close to the line of the Lordsburg and Clifton railroad, and an excellent wagon road to the camp. The district yields gold, silver and copper. The Carlisle mine is a gold mine. There was great excitement there when the discoveries were first made, but after the present company commenced operations the noise quieted down.

OREGON.

NOTES.—*Jacksonville Times*, May 18: The rains are keeping up what water supply there is. F. M. Blevins, of Siskiyou county, is in this section on a prospecting tour. Rich rock is being taken out of the old John Roten ledge on Kane creek. T. B. Hueston, of Thompson creek says the miners of that region still have plenty of water. The miners have made no extraordinary reports as yet.

UTAH.

A REVIEW.—*Tribune*, May 19: The movement of bullion for the week has been the smallest of any week this year, the receipts in this city for the week ending May 17th, inclusive, being \$87,613.46, as against \$132,451.12 the previous week, and \$173,724.51 the week before that. The shipments for the week ending May 12th, inclusive, were: 41 cars bullion, 1,045,894 lbs; 5 cars ore, 114,928 lbs; 1 car ore, 32,600 lbs; total, 47 cars, 1,193,422 lbs. The Horn Silver shipments of bullion were 14 cars, of the value of \$42,000; previously reported for the present calendar year, \$1,267,500; aggregate at this date, \$1,309,500. The quarterly dividend of \$300,000 was duly paid on time, May 15th. The week has been eminently one of preparation, and the signs of the resumption of summer's activity are on every hand. The opening of the Alta railway, the bettering of the canyon roads, and the departure of mining men hither and thither, all tend to the same purpose. The Crescent bonanza diminishes no what in interest. It sent in during the week 200 of ore (not counted in above receipts) that were sold here at satisfactory figures. A dividend of 10 cents per share, amounting to \$50,000, has been declared by the Crescent, payable June 20th. This company also advertises for proposals for hauling ore from its dumps for a year, on the basis of 60 tons per day, from which it will be seen that the intention of the management is business. The Sampson is also moving; there was received from it on the 12th (aside from the report of receipts above given) three cars of second-class ore, which netted the company a little short of \$40 per ton.

Santa Cruz Mountains.

We give herewith a sketch of the crowning height of the Santa Cruz mountains, Mt. Bache, or, as it is locally called, Loma Prieta, which is the name applied by the Spanish-Mexican population to any chaparral covered mountains which look black in the distance.

The entire system of elevations between the Bay of Monterey and the Golden Gate is sometimes included under one name, and called the Santa Cruz range, which is, however, properly the term for the southern and middle portions of the hills in question, or those included in Santa Cruz county. Here, in fact, are the highest mountains and the broadest belt of elevated country; the chain diminishing in height and breadth as it runs north, until it finally sinks beneath the ocean at the Golden Gate. The entire range, from the Bay of Monterey to the end of the peninsula, is about sixty-five miles in length, and its greatest breadth is about twenty-five miles. The eastern ridges are highly metaphoric, and constitute the main portion or backbone of the range, Mount Bache be-

for about forty miles. The northerly portion of this metamorphic ridge lies back of Mountain View, and of it Black Mountain is the culminating point, being about 3,000 feet high. Here are several parallel ridges which run out into the plain to the southeast, their strike taking them to the north of Mount Bache, the range being broken and irregular in the intermediate region, where cut through by the Los Gatos and Quito creeks. All these ridges have steep slopes, and are very dry in the summer and covered on their northeastern sides with dense chaparral, composed more exclusively of the *Adenostoma fasciculata*, or "chamisa," than were similar tracts farther south, where various species of *ceanothus* predominate in the dense, thorny and almost impenetrable growth, to which the name of "chaparral" is universally given.

The slopes on the southwest sides of the mountains were less inhospitable, being covered to a considerable extent with wild oats, as were also the foothills. The foothills in this region extend several miles into the San Jose plains, and are covered with a fertile soil; they form

Mineral Prospects near the Colorado.

The *Calico Print* says: Reports are constantly coming in from points along the railroad, between here and the Colorado river, in regard to the country which is now being prospected for mineral by numerous parties.

From what we hear, we conclude that there is a large area of fine mineral land in the eastern part of this county, which has only been partially explored, and which shows very favorable indications of immense quantities of hidden wealth, which will be extracted at no distant day, by the combined efforts of hardy miners and enterprising capitalists. The railroad has opened up a large extent of country, barren, desolate and apparently worthless, but which the indefatigable prospector has proved, by months of weary explorations, to be a land of gold, silver, copper, borax and other substances which are a source of wealth, now brought within the reach of even ordinary capital.

The greatest drawback to the prospector has been the scarcity of water; but now it can be obtained at any point on the railroad for two cents a gallon, by applying to the proper railroad officer, who will order the water car to stop at any convenient point for the benefit of prospectors.

The other day we obtained a few items of interest from S. W. Fulton, who has been out

Mining with British Capital.

English capitalists have no objection to putting a few sovereigns in mining enterprises whenever convinced that they will get them out again with a fair prospect of a few more. Accordingly they are working mines in nearly all the Pacific States and Territories. We simply wish at this time to note the operations of two English mines in California for the last half of the year 1882. These are the Plumas Eureka and the Sierra Buttes. The first-named produced 29,460 tons from its respective claims during that period. All this ore was reduced, besides thirty tons previously on the dumps. The ore yielded only \$6.60 in free gold, and yet it was worked at a profit, because the expense of mining, including prospecting, was only \$3.35, while the cost of milling was only forty-five cents per ton, making a total expense of \$3.80. The net balance for the half year was \$141,600, and out of this sum a dividend of \$70,313 was recommended. This has since been paid. The mine has given to its stockholders to date the sum of \$1,730,800. The Sierra Buttes mine produced 15,769 tons of ore during the same interval, all of which passed through the mill. The ore yielded \$7.48 per ton, or, including tailings, \$8.18. The working expenses were \$5.56, including \$4.98 for mining and prospecting and fifty-eight cents for

MT. BACHE (LOMA PRIETA), SANTA CRUZ MOUNTAINS, CAL.

ing the highest point; this has an elevation of 3,780 feet, being less than a hundred feet lower than Mount Diablo. This mountain mass, to which Mounts Choual (3,530 feet) and Ummuhum (3,430 feet) belong, is the dominating one of the range, although there are points farther north which rise to over 3,000 feet.

In crossing over from Santa Cruz, in a northerly direction across the chain, to the Santa Clara valley, before reaching the metamorphic, a mass of rocks is traversed which is much broken and elevated, some of the ridges being fully 2,000 feet high. In rising on to this elevated ridge, from an elevated point near the summit, an extensive view is to be had of the southern part of the range of the high and deeply eroded ridges of Mount Bache to the east, and of the ranges to the northeast, which are also lofty and rugged, rising in some places to nearly 3,500 feet in elevation. The scenery on this road from Santa Cruz to San Jose is hardly surpassed in grandeur and beauty by anything in the coast ranges. There are heavy forests of pine, firs and oaks, which almost vie with those of the Sierra in size and vigor of growth.

The metamorphic belt, before spoken of as occurring on the east side, forms the highest ridges of the range. The higher masses extend from a point back of Redwood City, southeast

some of the most delightful and attractive farming lands of the State and are now being largely planted with trees and vines.

The Santa Cruz mountain district is rapidly becoming one of the most famous in the State for rural improvement, and is certainly a most desirable district.

A NEW KIND OF BELT.—A new method of manufacturing belts or bands for machinery, which comes from Paris, is applicable to rubber, woven tissues of gutta-percha, and consists in making the belt in longitudinal belts or grooves, the main object of which is to increase the capacity of the belt on the same cross section, say twelve inches, by the extra strength put in the same space, and also to prevent so much stretching and variation. Another modification of the same invention is grooving one side of the belt the same as saw teeth, then putting these two pieces together, leaving a plain bearing surface for contact besides, thus making a double belt, which is less liable to stretch or to warp. Especial machinery is built for the purpose, and the claim for it is that better contact is given. The pores are closed during this grooving process, the belts have a higher resisting power, and do not twist on the pulleys. The grooves may be regular, irregular, spiral, or crossed.

SOME of the best mining authorities are now beginning to think that the main Comstock goes north, through Utah, instead of east, as heretofore supposed.

with Tom Ryan and Chas. Ells, prospecting in the vicinity of Sacramento Springs, a station seventeen miles from the Colorado by rail, and about six miles in a direct line. There are mines in this neighborhood that were worked twelve or fourteen years ago by the soldiers, who hauled their ore to the river, where it was loaded on the steamers that ply up and down the river. Thousands of dollars' worth of work was done on these mines, and the reason they were abandoned was on account of the Indians and the expense of transportation.

Recently some of these mines have been worked, and they are showing up well. A number of parties prospecting in the mountains there have taken up claims that look well. Mr. King, an assayer, is located there with his family, and is busy taking assays. He is interested in a number of mines with Messrs. David Nagle, Smith and Hoover. The latter is recorder of the district. Recently they shipped about six tons of ore to San Francisco, the highest assay of which reached \$2,900 to the ton. Messrs. Fulton, Ryan & Co. have secured some fine looking claims, and have brought in some specimens to be assayed. It is stated that there is an abundance of desert willow in the mountains where the mines are located, and plenty of other kinds of timber on the river. The formation of the ledges denote permanence. They carry silver and gold, and some copper. We were assured that a better country for prospecting could not be found. The miners there are sanguine that a bright future is in store for this section of country, and feel confident they will be richly rewarded for their labors.

milling. Excluding the work on the eight and ninth levels, the working expenses were \$4.15 per ton. The net balance for the half year was \$43,800, from which a dividend of \$30,625 was recommended. This has since been paid, and makes a total of \$1,460,300 given to stockholders to date. The accounts between the Company and the bankrupt firm of Cross & Co have been written off and finally settled. Here are two low grade quartz mines in this State that are being worked by English capital at a profit. Are there not other quartz claims of equal value now lying idle? Is it not possible for Americans to work mines in the same districts as cheaply as the English? We ought to do better with our mines than foreigners. It is a sad commentary on our enterprise and sagacity that Englishmen can do better with our resources than we can ourselves. There are large quantities of \$6 and \$8 Gold quartz rock in this State waiting development.—*Bulletin*.

It is said that the Homestake Mining Co., Black Hills, will erect a 200-stamp mill. It was only a few years ago that a sixty-stamp mill was the largest in that camp. Then came an eighty-stamp, and afterwards two 120-stamp mills.

THE Copper Queen mine, of Arizona, produced 1,138 tons copper in the first quarter this year.

A SAN FRANCISCO company purchased the Onondaga mine in Safford District, a few days ago, for \$112,000. Safford, the discoverer of the mine, is to receive one-third of this sum.

The Opium Evil at the East.

Our Eastern friends are waking up widely to the great vice of the Chinese, that of opium dissipation. They find, as we have found, that the Asiatics not only ruin themselves with the drug, but are enticing Americans, both young and old, into their base haunts, and accomplishing their physical and moral ruin. The reports from New York and Chicago tell of such revolting acts as the enticing of school girls into their base dens to be drugged and destroyed. In the degrees of crime this is the basest, and cries most loudly for condign punishment. They find also at the East that the vice has possessed itself of elegant apartments, and is gaining adherents among the women of the upper classes. Thus it is striking at the welfare of the whole people, and Eastern people fully appreciate that it must be stamped out with no gentle heels.

The action against the opium demons in New York city is brought by the priests of the Catholic church and they are deserving for credit for their summary and vigorous movement. They were most annoyed by the orgies of the Chinese, for their churches and people were in proximity to their worst strongholds. They suffered at first for their efforts, but they are now gaining the victory, for the officers of the law and public sentiment are now coming quickly to their aid. What has been done is thus described in a dispatch from New York on Wednesday morning:

Father Barry, of the Church of the Transfiguration, the society which is moving for the expulsion of the Chinese from Mott street, said to-day: "We have had no such Sunday for years in this neighborhood as the last. It was, at least, outwardly decent and orderly. We could get through the streets without being insulted, and the air was not made hideous by yells and loud talk that generally make Sunday here a pandemonium. So far, we have attained the only object we had in the beginning of this agitation—outward decency and order. As for opium smoking, I don't feel able to hope that it will be suppressed." Being asked if the matter will be brought formally before the Grand jury and legal proceedings instituted, he said: "I suppose that will be done. It is very difficult, however, to get correct evidence on the subject. We can all swear we have seen little girls go into these places and that they stayed there for hours. We know the character of the occupants, and we must draw our own conclusions. Of course it is a very difficult matter to get a confession from one of the interested parties, and if evidence of the commission of any iniquity beyond opium smoking is required as proof, we cannot produce it. All the decent residents of the vicinity, without distinction of race or creed, have come forward voluntarily and offered us their aid, and some of them have made tenders of money. That shows that there is no prejudice in the matter. Israelites, Protestants and Catholics have united in giving testimony to the existence of the evils, and in their offers of assistance to us."

Some of the leading journals of New York are apparently shielding the vile opium fiends with statements that there is no law which pronounces opium smoking a crime. If that be so, the sooner they make such a law, the better for the welfare of their people. They will find that the evil with which they have to contend, face to face, is no easy thing to vanquish. They will find that with the strongest laws they must exercise constant vigilance and act promptly and zealously, if they would save their young people from ruin and their old people from suicidal folly. It is only by constant work that the vice is kept within any bounds in California, and even with that, it is ceaselessly drawing its victims from all walks of life and bringing sorrow to many households. We have to fight it in city and in country. There is no need of being tender fingered about it or to attempt to bring it under the rank of class persecution. It is a vice which the Chinese authorities abominate and do their best to stamp out in the Empire, and the people of the United States owe it to their own safety and to the welfare of the sojourners among them, that the ways of the opium purveyors and users shall be made as hard as possible.

WHEN entry is made of a mining claim and the money paid for the land, the receiver of the local land office in which the claim is entered, fills out two receipts for the amount paid: one of these is transmitted with the final certificate of entry and the papers, and the application to the general land office. The other receipt is given to the purchaser. When patent is issued it is delivered to the party holding the duplicate receipt, who surrenders the same. An attorney for the owner, or any one else holding the duplicate receipt, can obtain possession of the patent. Usually this receipt is held by the attorney in the case, who holds it until he gets his fee.

MILL SITES.—By a recent ruling the claimants of mill sites are permitted to cut and remove timber thereon for the purpose of constructing mills, reduction works, tramways, or other accessory required in developing their mining interests. In permitting the removal of timber from a mill site, or tract of non-mineral land prior to the issuance of a patent therefor, it is strictly forbidden to make such timber an article of sale for private gain or speculation.

USEFUL INFORMATION.

Painted Diamonds.

The latest fraud in precious stones furnishes a serious confirmation of the law of chromatic contrasts, and an unexpected illustration of Shakespeare's saying:

To gild refined gold, to paint the lily.

About six months ago, the owner of a magnificent gem, which he had supposed to be a Brazilian diamond of the first water, suddenly found it reduced to about one-fifth its value by being accidentally washed with soap-suds. This simple process revealed its true character as a yellow African diamond of inferior grade. This trick, which was originally played in Paris, has since been reproduced in this country, and, it is rumored, that a single firm on Chatham street was thus windled out of many thousands of dollars without being able to detect the perpetrator of the fraud.

A case of the sort is now in the New Haven courts, being tried by Judge Denning, some of the particulars of which may be of interest, and serve to put persons on their guard against what is really an ingenious deception:

Jacob Nepel, a manufacturing jeweler in that city, had several diamonds, apparently of great value, which he disposed of by an agent to Mr. Edward Engel, a diamond broker of seventeen years' experience. The gems were faultless, but the low price set on them awoke suspicion that they were either stolen or spurious. Several local dealers examined them, using a microscope for the purpose, and pronounced them fine old mine diamonds, and worth five or six times their price. Mr. Engel then took them to New York, and exhibited them to Messrs. Heller & Bardell, importers and dealers in precious stones, who were also deceived by the appearance of the gems, until the owner mentioned his suspicions. Mr. Heller, remembering to have heard of a new process of painting diamonds, took one of the studs, estimated to be worth from \$1,000 to 1,500, washed it in soap-suds, and found it to be a cheap African diamond, worth perhaps \$140. The rest of the set proved to have been tampered with in a similar manner. On returning to New Haven, Mr. Engel sought redress through the courts, and probably will get it.

The explanation is as follows: The common African diamonds are naturally a honey-yellow. On dipping one of them for a few minutes in an aqueous solution of aniline violet, and then letting it dry, it will be found that, while the luster remains unimpaired, the color is changed from yellow to the fine steel-blue usually observable only in the best stones. The two colors, yellow and violet, it will be noticed, are complementaries, and, on blending, produce the brilliant result described. The aniline is easily removed by the application of soap-suds, the water being tinged, not violet, but green, while the diamond regains its original yellow hue.—*Scientific American*.

A USEFUL KIND OF SOLDER.—A soft alloy, which attaches itself so firmly to the surface of metals, glass, and porcelain that it can be employed to solder articles that will not bear a very high temperature, can be made as follows: Copper dust obtained by precipitation from a solution of the sulphate by means of zinc is put in a cast iron or porcelain lined mortar, and mixed with strong sulphuric acid, specific gravity 1.85. From twenty to thirty or thirty-six parts of the copper are taken, according to the hardness desired. To the cake formed of acid and copper there is added, under constant stirring, seventy parts of mercury. When well mixed, the amalgam is carefully rinsed with warm water to remove all the acid, and then set aside to cool. In ten or twelve hours it is hard enough to scratch tin. If it is to be used now, it must be heated so hot that when worked over and brayed in an iron mortar it becomes as soft as wax. In this ductile form, it can be spread out on any surface, to which it adheres with great tenacity when it gets cold and hard.—*Polyt. Notizblatt*.

LAYER BREAD is made of a seaweed (*Porphyra laciniata*) found growing on the low rocks. The women gather it in large baskets and carefully pick it over, wash it, and then pick out any other sort of seaweed that may get in with it. It is then thoroughly washed again to remove all the sand, after which it is boiled for about two hours, then chopped up with a knife, rolled into lumps, and sprinkled with oatmeal to keep it together and make it look clean. It is only made along the Glower and Devonshire coasts, where a great many women earn their living by making it. After it is cooked it will keep for about three or four days in summer, and for about a week in winter. Most of it is taken to the Swansea market, for which a great deal is sent from Devonshire, where the seaweed grows more abundantly than about Glower. It is sold at 3d., 4d., and 5d. per pound. The poor people are very fond of it, and eat it either fried with bacon grease, or else cooked like a vegetable with meat.—*Kerr Report*.

FLUX FOR IRON OR STEEL.—It may be useful for some of our readers to know that a flux for welding iron or mild steel can be made as follows: Take one part of lime to two or three parts of river sand, such as a plasterer would use for a finishing coat.

THE EFFECT OF HEAT ON FLOUR.

It frequently happens that wheat or rye flour, in spite of the greatest care in baking, yields an inferior loaf, and the failure is commonly attributed to adulteration; but when submitted to investigation, neither microscopic nor chemical tests reveal any adulteration. Such flour is returned to the miller or dealer as unfit for use. The miller says the flour was injured by the heating of the stones, and the dealer attributes the defect to the circumstances that the sun must have shone upon the sacks during transportation. It has been proved by numerous experiments that flour cannot bear the action of the sun, even when not exposed directly to its rays. When flour is exposed to the heat of the sun an alteration takes place in the gluten similar to that produced by the heating of the stones. For this reason it is advisable that the transportation of flour should take place, if possible, on cool days or by night, as well as that flour should be stored in a cool place. *Boston Journal of Chemistry*.

UTILIZATION OF DISEASED POTATOES.

A correspondent of the *Journal of the Society of Art*, says: I know from practical experience that M. Bourlier and M. Herve are quite correct as to the value of diseased potatoes as an article of food for cattle, pigs, etc., but the most important item to be observed they omit in their directions, which I revise as follows: Boil the diseased tubers fast till done; drain, and let them become perfectly dry by spreading them out on sieves—a gravel screen is the best. The tuber, when cooked, is free from poison; the water in which it is boiled is very strong poison, and will scorch, if not kill, any animal that partakes of it. When dry, run tight into any kind of dry cask (with salt), and keep in a cool place till wanted. One boiler full can be dried and packed while the next is cooking, so that a large quantity can be cooked in one day. Every farmer should know this, as it would save him suffering any loss, however bad his crop might be.—*Geo. Wm. Pissall*.

COLORING PHOTOGRAPHS.

A new method of coloring photographs has been patented by Mr. Jesse W. Hyman, of Englewood, N. J. The process consists in immersing the photographs in a solution of naphtha, paraffine, mastic drops, ether, and vinegar, and applying to the back, in oil paint, the desired shade and tone, and also applying a mixture of glue and glycerine to the back and pressing the back to canvas until cohesion takes place, whereby the whole picture will be flexible and have the appearance of having been painted on the canvas.

GOOD HEALTH.

Chills—Their Causes and Consequences.

Catarths should receive careful consideration, instead of the neglect which they generally meet with until they have fastened on the part affected so much as to excite the attention, and perhaps alarm, of the sufferer. Here, however, we propose to say a few words about the causes of chills.

A person in good health, with fair play, easily resists cold. But when the health flags a little and liberties are taken with the stomach or the nervous system, a chill is easily taken, and according to the weak spot of the individual, assumes the form of a cold, or pneumonia, or, it may be, jaundice. Of all causes of "cold," probably fatigue is one of the most efficient. A jaded man coming home at night from a long day's work, a growing youth losing two hours' sleep over evening parties two or three times a week, or a young lady heavily "doing the season," young children at this festive season overfed and with a short allowance of sleep, are common instances of the victims of "cold."

Luxury is favorable to chill taking; very hot rooms, soft chairs and feather beds create a sensitiveness that leads to catarrhs. It is not, after all, the "cold," that is so much to be feared as the antecedent conditions that give the attack a chance of doing harm. Some of the worst colds happen to those who do not leave the house or even their bed, and those who are most invulnerable are often those who are most exposed to changes of temperature, and who, by good sleep, cold bathing, and regular habits preserve the tone of their nervous system and circulation.

Probably a good many chills are contracted at night or at the fog end of the day, when tired people get the equilibrium of their circulation disturbed by either over-heated sitting rooms or under-heated bedrooms and beds. This is especially the case with elderly people. In such cases the mischief is not always done instantaneously, or in a single night. It often takes place insidiously, extending over days or even weeks. It thus appears that "taking cold" is not by any means a simple result of a lower temperature, but depends largely on personal conditions and habits, affecting especially the nervous and muscular energy of the body.—*Lancet*.

CURE FOR IRY POISONING.—Bathe the parts affected with sweet spirits of nitre. If the blisters be broken, so as to allow the nitre to enter the cuticle, more than a single application is rarely necessary; and even where it is only applied to the surface of the skin three or four times a day, there is rarely a trace of poison left next morning.

A MOTHER KILLED BY SUDDEN JOY.

Joy is said sometimes to kill outright, though such cases are extremely rare. A perfectly authentic and quite recent instance of such an occurrence may be worth recording. A certain Mad. Laroche, who kept a little mercer's shop in Paris, had a son who, when his turn came for conscription, unfortunately drew a "bad number," and had to go as a marine to Saigon, where he remained several months. He was then transferred to Guadeloupe; but the letter in which he announced the fact to his mother never reached her. She continued writing to Saigon; and, as her letters received no reply, she fell into a State of profound despair, and concluded that her son was dead. Recently, however, the young man, having leave to return to France, unexpectedly presented himself in his mother's shop and threw himself into his mother's arms. The poor woman, stupefied at his sudden apparition, uttered a cry of joy, then all at once she reeled and fell dead to the floor.

POISONOUS PAPER.

Eighty-four samples of colored paper, supplied by a Massachusetts firm for the use of Kindergarten pupils, show arsenic to be present to a considerable extent in a large number of the papers, and in eight of the specimens, to a dangerous degree. These strips of paper are used by the children in weaving various designs, and, of course, this work is a most natural occasion for the use of nature's unclasp the saliva. The manufacturer, indeed, calls attention to the fact that the most attractive colors contain arsenic cannot, indeed, be made without it, but suggests that there is no danger if the children be taught to work with their mouths shut. Even if a child could be taught to overcome its nature enough to keep things out of its mouth, while it might in a measure diminish the risks from lead and other poisons used in the same papers, it is hardly necessary to say that it would be far from removing the exposure to arsenical poisonings.—*The Medical News*.

THE PULSE OF ANIMALS.

In horses, the pulse at rest beats forty times, in an ox from fifty to fifty-five, and in sheep and pigs about seventy to eighty beats per minute. It may be felt wherever a large artery crosses a bone, for instance. It is generally examined in the horse on the cord which crosses over the bone of the lower jaw in front of its curved position, or in the bony ridge above the eye, and in cattle, over the middle of the first rib, and in sheep by placing the hand on the left side, where the beating of the heart may be felt. Any material variation of the pulse from the figures given above may be considered a sign of disease. If rapid, hard, and full, it is an indication of high fever, or inflammation; if rapid, small, and weak, low fever, loss of blood, or weakness. If slow, the probabilities point to brain disease, and if irregular, to heart troubles. This is one of the principal and sure tests of the health of an animal.

FOR COLD FEET, or bad smelling feet, ventilate the dark dungeons in which they are confined. Wear loose boots, and, so far as practicable, low shoes. Have a relay—a second pair—so that one pair can be airing all the time. Active walking or running warms the feet, but unless the stockings are changed and the feet put into loose slippers, directly after the exercise, less advantage is gained. For bad cases of this disease, exercise the bare feet, go barefoot upon all practicable occasions, as tramping up and down the beach when at the seashore, etc. Improve the living habits at all points. Eat plain food, chiefly meal, fruit and vegetables, and be temperate in eating as well as drinking. Thus shall the circulation be made and kept pure, and caused to flow to the extremities to keep them warm, while cleanliness, in the ordinary sense, will then keep them clean.

TO PREVENT THE SKIN FROM DISCOLORING AFTER A BLOW OR FALL.

Take a little dry starch or arrowroot, and merely moisten it with cold water, and lay it on the injured part. This must be done immediately, so as to prevent the action of the air upon the skin. However, it may be applied some hours afterwards with effect. I learned this when a resident in France. It may already be known here, but I have met with none among my own acquaintances who seem to have heard of it. Raw meat is not always at hand, and some children have an insurmountable repugnance to let it be applied. I always make use of the above when my children meet with an accident, and find that it keeps down swelling, and cleanses and facilitates the healing of scratches when they happen to fall on the gravel in the garden.—*Popular Science News*.

PREVALENCE OF CANCER.

It appears from figures taken from the records of the Board of Health, that cancer—most shocking of all diseases—is a fast-spreading evil in New York city. In 1869, as appears, it was the cause of 304 deaths, a proportion of about one in a hundred of all the deaths recorded. In 1879, 572 persons died of cancer, or about two per cent of all who died within the year. In 1880, there were 659 fatal cases of the disease, a startling increase, and a total greater than that of the victims of scarlet fever in the year.

SAN FRANCISCO:

Saturday Morning, May 26, 1883

TABLE OF CONTENTS.

EDITORIALS.—Lodes in Placer Claims; California
Iron; Huntington's New Crushing Mill; Influences on
Shots in Blasting, 353. Passing Events; Surface
Ground of Lodes in Placer Claims; Gold for Blowpipe
Examinations; Foundry Notes; Local Astronomical
Observations, 360. Notes from Eureka, Nevada; New
Rotary Crusher, 371. Patents and Inventions; Notices
of Recent Patents; English Investments in Pacific Coast
Mines—No. 5, 364.

ILLUSTRATIONS.—Huntington's Centrifugal Roller
Quartz Mill; Primitive Method of Grinding Ore, 353.
Mt. Pacheco (Loma Prieta), Santa Cruz Mountains, Cal.,
353. Arrangement of Vertical Timbers for Supports;
Temporary Timbering in Circular Shafts, 361.

MECHANICAL PROGRESS.—Lubrication; Casks
and Barrels of Steel; Insulating Wire; A Reminiscence
of Blacksmithing; Steel, Steam, Gas and Water Pipe;
Large Gun-Boring Machines; A Novelty in Fire-Proof
Structure; American Engines in London, 355.

SCIENTIFIC PROGRESS.—The Visibility of
Ruled Lines; The Volatilization of Solids; Putting Pelagic
Animals to Sleep; West Indian Phosphate; An
Ebonite Thermometer; Production of Sulphur in the Soil
of Paris; Dust, Mist, and Clouds, 355.

MINING STOCK MARKET.—Sales at the San
Francisco Stock Board; Notices of Meetings, Assess-
ments, Dividends and Bullion Shipments, 356.

MINING SUMMARY.—From the various counties of
California, Nevada, Arizona, Colorado, Idaho, Mont-
ana, New Mexico, Oregon and Utah, 356-7.

USEFUL INFORMATION.—Painted Diamonds;
A Useful Kind of Solder; Flux for Iron or Steel; The
Effect of Heat on Flour; Utilization of Diseased Potatoes;
Good Coloring Photographs, 359.

GOOD HEALTH.—Chills—Their Causes and Conse-
quences; Cure for Ivy Poisoning; A Mother Killed by
Sudden Joy; Poisonous Paper; The Pulse of Animals;
Cold Feet; To Prevent the Skin from Discoloring after a
Flow or Fall; Prevalence of Cancer, 359.

MISCELLANEOUS.—Early History of the Com-
stock—No. 4; Arizona Outlook; The Coming State;
Black Hills Copper Mine; Marysville, 354. Santa
Cruz Mountains; Mineral Prospects near the Colorado;
Mining with British Capital, 358. The Opium Evil at
the East, 359.

NEWS IN BRIEF—On page 364 and other pages.

BUSINESS ANNOUNCEMENTS.

Mining Engineer—Otto Hermann, S. F.
Irving Institute—Rev. E. B. Church, S. F.
Anderson Springs—Anderson & Petriquin, Lake Co., Cal.

Passing Events.

A very important event for this State was the
starting up this week of the iron furnaces in
Placer county, and as the iron is of fine quality
it will be an exceedingly useful product for
California.

The great Brooklyn bridge was formally
opened on the 24th inst., and is now used for
regular traffic. This marks an era in the engi-
neering world.

The opening of the National Exhibition of
Railroad Appliances at Chicago this week is
another important industrial event. California
will be represented there by several important
inventions which are practical in their nature.

The laying of the foundation stone of a new
astronomical observatory this week is a matter
of interest to local scientists.

The general news from the mining regions is
quite encouraging in its nature. Miners every-
where are busy and the business of mining is
gradually gaining in public esteem as legitimate
work is steadily pursued, while stock gambling
is on the decline.

LEWIS E. ARCHERSON, long and favorably
known as a mill man of much experience, and
as an assayer of more than ordinary ability, and
highly esteemed for his personal qualities in
many of the camps of the coast, died recently
at Richmond, Indiana, of pleuro-pneumonia.
His last professional engagement was with the
Hope Mining Company, of Phillipsburg, Mont-
ana.

Surface Ground of Lodes in Placer Claims.

The Commissioner of the General Land Office
a short time since held for cancellation an en-
try of lode claims in Montana, because
the ground covered thereby had been previ-
ously patented as placer claims, said pat-
ents having been issued in April and May, 1881.
It appears that the lode applicants located their
claim May 5, 1879, filed application for patent
November 2, 1880, notice whereof was regularly
published from November 5 to Jan. 6, 1881,
whereupon they made mineral entry No. 611,
January 14, 1881. Their application calls for
"1,497 linear feet of the Shonhar vein, lode or
deposit, bearing silver and other metals, to-
gether with surface ground, varying from 464
to 538 feet in width * * * in the Summit
Valley Mining district, Montana." It appeared
that affidavits were filed of persons resident in
said district, alleging that the Shonhar lode is a
well defined vein, rich in minerals, and that its
existence was known at, and long anterior to,
the date of said placer application.

The Secretary of the Interior, to whom the
case was appealed, says the case, so far as it re-
lates to the question of the existence of a known
lode, is within the rule established by the De-
partment in the matter of the Mammoth Quartz
mine, wherein it was ordered that the lode
claimants be permitted to proceed pursuant to
statutory provisions by application for patent
upon the lode claim, by regular publication,
subject to the filing of an adverse claim and by
institution of suit in a court of competent juris-
diction. This case we refer to in another
column of this number of the PRESS.

In rendering his decision the Secretary of
the Interior says: "But the present claim ex-
ceeds twenty-five feet in width, on each side of
the vein. The application has been allowed,
publication regularly had, and the entry made.
In fact, said claimants had completed their
proofs, and the same were matter of record in
your office, for several months prior to the is-
sue of the placer patents, and no adverse
claim was filed. It would not be practicable,
therefore, at this stage of the case, to remit
these claimants to the performance *de novo* of
such preliminary requirements. In the absence
of an adverse claim they are entitled to take
their lode and twenty-five feet on either side.
The only question remaining is whether or not
the excess over that width of surface ground
can be allowed. I think this cannot be done.
The lode claimants, in order to protect their
right to the full extent of their claim, should
have filed adversely to the placer application
within the statutory period; but, having failed
so to do, they are expressly restricted by the
statute to their lode, 'and twenty-five feet of
surface on each side thereof.'"

The decision of the Commissioner of the Land
Office that patent could not issue to the lode
claimants was, therefore, reversed by the Secre-
tary of the Land Office, who directs the patent
to the lode to issue, on the filing of a cor-
rected plat properly defining the restricted sur-
face grounds.

Gold for Blowpipe Examinations.

Gold for blowpipe examinations should be
pure, especially for assays of nickel and copper.
The most convenient form will be found to be
that of a thin foil. If not procurable it can be
prepared as follows: Take a piece of gold coin
and fuse it with three times its weight of silver,
and when in the state of fusion pour into a ves-
sel containing cold water. Collect the granula-
tions thus formed, and dissolve in a flask or
beaker glass with diluted nitric acid. After
boiling for fifteen or twenty minutes decant
carefully, and wash the gold residue with dis-
tilled water; then attack the gold with strong
nitric acid (1.30 specific gravity) for twenty
to thirty minutes. Decant and wash repeatedly
with warm water, then add nitro-hydrochloric
acid and boil until the gold is completely dissolved.
Dilute with water, warm slightly, allow the
solution to settle for about 24 hours, then decant
and add oxalic acid slightly in excess. The
mixture of trichloride and acid to be heated
gently. The precipitation is slow, but is greatly
assisted by heat. When finished, decant and
wash on a filter; afterwards heat over a gas or
lamp flame in an evaporating dish or capsule.
The gold is easily reduced by this means to a
metallic state; then fuse and cast into an addi-

tion of bisulphate of potash, and cast into an in-
got, or any other desirable shape. The gold
can be beaten or rolled into thin foil, and it is
then ready for use.

Mr. George Atwood, in his work on "Blow-
pipe Assaying," recommends the addition of
bisulphate of potash as an extra precaution in
case that a slight trace of silver should still re-
main with the gold before the fusion.

Foundry Notes.

Within the past few months there has grown
up on the shores of San Francisco bay, one of
the largest manufacturing establishments on the
Pacific coast, and which would do credit to
much older communities than our own. The
ground for the works of the Jud-
son Manufacturing company was not
broken until about July 1st, of last
year. Since that time the company has erected
extensive buildings, manufactured tools and
machinery, systematized a large business and
built up a thriving trade, which is rapidly in-
creasing. The works are in the western part
of Oakland, near Emery station, on the line of
the Central and Southern Pacific Railroad and
on the edge of the bay shore. The water front
forms one boundary of the grounds, and the
overland railroad track the other.

A representative of the PRESS recently vis-
ited these works, and like other visitors for the
first time, was surprised at the magnitude of
the "plant" and the marked evidences of
rapid growth which were everywhere seen.
In each of the large buildings are scores
of busy workers intent on allotted tasks,
each doing some one thing or preparing some
one part of the products of the establishment.
Ponderous engines, curious machines, blazing
furnaces and ingenious tools occupy their proper
places; and one may watch a mass of rough
iron come in one door and follow it through
the various processes until it goes out another
in the form of nails, tacks, hardware, agricul-
tural implements, or any of the various pro-
ducts of the place. The buildings themselves
are plain, but light, airy and clean, and it is
apparent that the comfort, health and
convenience of the employees has been consid-
ered, as the matter of light and ventilation has
not been neglected. The establishment is di-
vided into departments, each of which is sepa-
rate in itself, and distinct from the others. The
moving machine shop, foundry, file works, tack
works, paint shop, wood shop, etc., each has its
building and allotted space, and what is more,
each department has its superintendent, who
has his own private office, where he attends to
all in his department.

Without going into any detailed description
of the engines, boilers, the wood or iron-work-
ing machinery, tools or utensils, it will be
enough to say that in its equipment the estab-
lishment is very complete, the machinery in
every department being the most improved and
recent patterns. No expense has been spared
in procuring the very best appliances of all kinds.
Iron tracks are laid all about the grounds, so
that hand cars are used to facilitate the hand-
ling of material. The grounds are all sewered,
and the buildings stand well up off the ground
on brick piers, so the air passes freely under
them. The tide flows each day to the edge of
the grounds, carrying off debris, and the fresh
trade winds come unobstructed from the Pacific
ocean through the Golden Gate, right over the
works.

This company has adopted the plan of mak-
ing its own machinery and tools whenever prac-
ticable, and in their machine shop may be seen,
in all stages of preparation, tack and nail ma-
chines, file machines and tools, and all the var-
ious implements which are used in manufactur-
ing the products of the establishment. There
are lathes, drills and all the tools necessary to
do the very best style of mechanical work.

In the tack factory may be seen the men cut-
ting, by the aid of machines, the flat iron into
strips. There is a pickling room where the iron
is put through a process of pickling to
take off the scales. Going up above by
the elevator, we find a busy scene, where are
the tack and nail machines to manufacture some
200 kinds of nails and tacks, from the tiny iron
tack to the two inch clout nail. There are
twenty machines in this room, and very inge-
nious they are in construction and operation.
Many of them were made on the premises.
Down stairs again we visit the polishing room,
and then the tinning department where the
tacks are tinned. Near by is the bluing room
where the tacks are "blued." Opposite is a
packing room where girls pack up and label the
tacks, ready for market. This industry is an
entirely new one on this coast.

The Judson File Works forms a new in-
dustry on this coast, and having a capaci-
ty of 100 dozen a day. These files have
been tried by the best mechanics and proved
equal to anything ever imported into this mar-
ket. In these rooms are cushioned steam ham-
mers, grind-stones, file machines, etc., for mak-
ing all varieties of files.

In the coal building, they now have on
hand 4,700 tons of Australian coal. From here
railroad tracks are laid and the coal conveyed
to where it is used in the buildings. In the
rolling mill building, the rolls are now turn-
ing out bar and flat iron for the manu-
factures of the establishment and for the gen-
eral market. It was intended to have a capaci-
ty of 30 tons a day, but seems to be doing more

work than that. The furnaces in this mill con-
sume their own gas and smoke; and a magnifi-
cent large engine runs the rolls. The building
is light and airy, and all the arrangements are
well carried out.

There are now some 240 men employed at
these works, but when in full running order it
is expected that 1,100 will be employed. Dur-
ing a couple of months this year they ran night
and day, though now only day work is being
done.

Among the varieties of hardware manufac-
tured at these works are barn-door hangers,
barn-door rollers, rails and pulls, well wheels,
blacksmiths' tyere iron, bench screws, wheel-
barrow wheels, cast washers, carpenters' and
farmers' sledges, and round and square-faced
sledges, hitching weights and posts, wine press
screws, etc. The Judson horse shoe nails form
another very important branch of local manu-
facture. In California Victor Mowers alone, a
large trade is being built up, as they are turn-
ing out ten mowers a day and have built
over 1,000 this season.

The company possesses exceptional facilities as
to site, appliances and resources. They control
the Clipper Gap Iron mines at Clipper Gap,
Placer county, in this State.

From these mines a superior article of iron is
produced, and the new furnaces are now turn-
ing out a large quantity of pig. This is the
largest iron mine on the coast. These works
will use this iron in their manufactures to a
large extent hereafter. Mr. Egbert Judson,
President of the company, was the pioneer
mover in this enterprise, as he has been in sev-
eral other home industries in this State.

Local Astronomical Observatories.

During the past week, the corner-stone of a
new astronomical observatory was laid in Oak-
land, with suitable ceremonies. The observa-
tory is the gift, to the city of Oakland, by a gen-
erous citizen, Mr. A. Chabot, and is intended
particularly for the use of students of the pub-
lic schools of Oakland, and vicinity. Mr.
Chabot does not make any provisions or prom-
ises, but puts the coin in the bank to be drawn
upon, and says, "Go ahead," and they are go-
ing ahead. The telescope is to be a refractor
of eight and one fourth inches aperture,
and will be mounted on a fine substantial pier
30 feet above the ground, and protected by a
suitable dome. All the necessary appli-
ances will be available, and arrangements will
be made for transit observations. The gift is a
timely and handsome one, and science has
reason to be grateful to Mr. Chabot for his gen-
erous disposition.

San Francisco, Berkeley and Oakland will
soon be very well equipped with respect
to telescopes. Capt. Charles Goodall is about
purchasing a large one, which he will put up in
an observatory on his residence. The Board of
Regents of the University of California are about
to order a good instrument for the University,
so the students there will be able to make
observations.

In addition to these, Mr. Charles Burkhalter,
a young gentleman of Oakland, has a four and
a half inch instrument with equatorial mount-
ing, which he has been using some months. Mr.
Burkhalter is an amateur, but did good work
on the occasion of the transit of Venus. He
has constructed a substantial brick pier on
which to mount his instrument, and has himself
made a light revolving dome of wood and can-
vas, so he has now a complete observatory.

The mechanism for the equatorial mountings he
made himself, and he also mounted and ad-
justed the instrument. The whole observatory
is a very creditable job, and as the glass is a
good one, Mr. Burkhalter can do good work.

Berkeley and Oakland, with three large tele-
scopes, are well provided for. It seems strange
that no public-spirited citizen of San Francisco
has come to the front with a telescope for the
public school children. There is only one good
telescope here, and that is a private one,
at the "Davidson observatory," belonging to
Prof. George Davidson, of the U. S.
Coast Survey, and President of the California
Academy of Sciences. He has been very
obliging with it and given many an opportunity
for observation, sometimes to his own inconven-
ience. The instrument is six and one half
inch aperture, by Clark, and is a fine one of its
size.

It seems probable that this State will become
somewhat noted in the matter of astronomical
observations, for we are to have the Lick tele-
scope, of 36 inches, at Mount Hamilton some of
those days, whilst the telescope now mounted
there is a Clark of twelve inches aperture.
There will be a full corps of astronomers, and
the observatory will be completely equipped
with all the necessary appliances; means will be
provided for prompt publication of all important
facts. Great things are expected from the large
telescope in a region where the atmosphere is
exceptionally clear and steady.

Notes from Eureka, Nevada.

[From Our Regular Correspondent.]

On the 19th inst. the personal property of the Albion Company was sold at Sheriff's sale, and thus the company have been relieved of a large portion of their indebtedness. The mine is gradually improving, and great hopes are entertained for entire relief from its present embarrassment.

The Lucan shaft of the Eureka Con. mine has been sunk 20 feet during the past week, and the ground being easier to work than heretofore, an additional 20 feet will be made during the coming week. Drifting towards the ledge will shortly be commenced, when I do not doubt that the mine will be soon placed strong on its legs again.

The Tributary.

In the Phoenix and Jackson mines, have been taking out considerable ore. Two young boys, Hancock and Keefe, have been industriously assorting over the old Jackson dump for several months past, and have displayed remarkable judgment for lads so young, neither of them being over 15 years old. They have paid several hundred dollars tribute to the company, and make a nice profit for themselves. Such enterprise in these youths is highly commendable. Messrs. Robert Waters & Co., who have been leasing the Grant mine on McVoy, or Mineral hill, for the past two years, have taken out several small pockets of ore from time to time, and in running a drift to connect the Geraldine tunnel with the old Grant incline shaft, discovered a rich vein about three weeks ago. Since then they have followed the ore which has opened up, and is now about four feet thick. The vein is of high grade quartz, and in the centre is a very rich character of black metal and yellow chloride, some of which assays as high as \$2,000 per ton. For some time past the ground in the Silver State tunnel has looked very favorable for ore, and a few days ago a strike was reported, but owing to press of business I have not had time to visit it. In the neighborhood of these mines, the croppings are either of massive iron or small blossoms of rich ore.

The Magnet series of mines which lay to the southward, upon the same belt, and to which adjoins the Eureka Tunnel mine, is evidently one of the great properties, that, with development, will in the future become a great ore producer, but for want of capital to open it in good shape little is heard of it.

The Eureka Tunnel

Was never in a more prosperous state than now. The ore being sent up from the North Addison chamber is the richest for the quantity that has ever been taken from the mine. The best of it is being stored in the office, under lock and key, and the entire mass is rich. The South Addison chamber is still yielding good ore. A drift has been started from the engine shaft going north from the 105-foot level, the face of which is in ore somewhat mixed with lime, the ore, however, being rich and easily separated.

The engine shaft is now down 119 feet. Sinking has lately been retarded, but to-day one of the ropes was taken into the tunnel and placed upon the reel, and the other will be put on tomorrow. The cage will be swinging on Wednesday, when the guides will be put in, and all will be in readiness to steam up and resume sinking on Saturday morning. Then look out for an increase in the output of the mine.

At the Alexandria, work is progressing finely, and this mine will soon be heard from.

The Sunset mine has been leased to parties who are highly encouraged with their prospects, and expect to be shipping ore by June 1st.

The Frankie Scott Con. is yielding some good ore, and the Antelope mine, although but little is said about it, is looking better than ever, and the ore is increasing.

Another new strike has been made in Dead Broke mine, but these strikes are becoming so common that the one is no more than reported when another is made. It is a fine property. A valuable strike has also been made in the Dug Out mine. A ledge six feet in thickness has been uncovered in the main tunnel, one foot of which is solid carbonate of lead. A large quantity of rich ore is being extracted from around the old Chambers from where, but a few weeks ago, some beautiful specimens of native wire silver were taken.

The ore output in the Home Ticket mine is increasing, and its neighbor, the Golden Rule tunnel, is showing a really good prospect.

A quantity of very heavy rich lead ore is being uncovered in the Altoona mine on Adams hill. The formation around it is of even grade quartz.

The Republic Mine

On Prospect mountain, is worthy of special notice. A great deal of good ore has been taken out of it lately, and its prospects are above the average of Prospect mountain mines. It has been opened by a vertical shaft, down 40 feet, to a natural cave going down an additional 80 feet, at the bottom and on the sides of which is quartz ore of good quality. All of this is intermixed with carbonate ore. A tunnel has been started, entering the hill at a point calculated to strike the cave at or near the top of it. Twenty tons of ore was shipped to the Richmond furnaces a few days ago, and five tons per day can easily be extracted from the mine.

The Ganges shaft is down 80 feet, and two men are at work in it, taking out a little high grade ore.

There are three men working in the Industry mine, prospecting, and taking out some good ore. The mines of the

Outside Adjoining Districts

Are showing marked progress. Mr. A. G. Rich, of the Enterprise Mining and Irrigating Co., Diamond district, came up from San Francisco last week, and visited the mine. He is evidently pleased with the outlook, as the crew

about 100 feet below the surface. Here the ledge is six feet thick, and two feet in thickness of it is of high grade ore, the balance being of good quality.

At Secret Canyon

The mines are all looking well. Some very high grade ore is being shipped from the Irish Ambassador (the way the name of the mine is recorded, M. H. S. mine.) The

FIG. 1.—ARRANGEMENT OF VERTICAL TIMBERS FOR SUPPORTS.

tion of concentrating machinery upon the ground is to be the result of this visit. When completed more active operations will take place upon the company's property, which is a very extensive one. It is expected that an average of twenty tons of rich ore and concentrations will then be shipped to the furnaces at Eureka per diem. It is estimated that there

Monitor mine main shaft is down twelve feet on a vein of rich ore, which is crossed by a gash vein of quartz. A tunnel is being run to strike under the shaft at a depth of about 250 feet, and although it is only one half the distance it is intended to run it, is showing splendid mineral indications. Some good prospecting is being done in the Metaline mine, and a large

FIG. 2.—TEMPORARY TIMBERING IN CIRCULAR SHAFTS.

are at least 50,000 tons of ore in sight, stripped, and ready to be broken down. The deepest working upon the ledge which carries ore continuously from top to bottom, is about 300 feet. This is known as the Mammoth Ledge, and from it Mr. Phillips, the Superintendent, kindly brought in a fine specimen this morning. It is a nice piece of ore, weighing about ten pounds. Its assay value is \$196.65 in silver, and it carries also sixty-three per cent of lead. It was taken from the Mammoth Ledge, at

quantity of quartz ore, full of chlorite and black metal, is being sent to the surface.

Pinto District.

Active preparations have been commenced upon the Rescue mine, at Silverado, from which good results are anticipated to be derived at an early day. The usual quantity of rich ore is coming from the Queen mine.

A rich strike has been made during the week in the Western Globe. The Fair Play has been leased, and operations resumed, with fine pros-

pects ahead. A patent will shortly be applied for upon the White Rose lode. There is a large pile of quartz and lead ore upon the dump, and the mine looking well, although work upon it has been suspended for the present. A tunnel is being run on the contact of two formations in the Diana mine. This work is intended to systematize the development of the property, which shows considerable ore in sight in the old works. The Berryman Tunnel is progressing slowly, but the work is being done with due regard to economy. A fine prospect is the Ettie Goodman mine, lately located in Pinto district. It has a ledge three feet thick from the croppings, running down to a depth of 20 feet from the surface. It increases rather than diminishes; the ore assays from \$14 to \$35 per ton in silver, and carries a trace of copper. The center of the vein is quartz and yellow carbonate ore. As I have been predicting, Pinto district is receiving renewed attention from prospectors this year, and will no doubt wind up the season prosperously. M. H. JOSEPH.

Eureka, Nev., May 21, 1883.

New Rotary Crusher.

David Bushman, of Quincy, Plumas county, has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency, a new form of rotary ore crusher. There is a casing or mortar having at one end a hopper through which ore is fed to the mortar. In the bottom of the mortar, near one end, is a die, made removable. Mounted transversely in the mortar is a shaft, and rigidly secured to this shaft are two disks, under the mortar. Heavy beaters are pivoted between these disks by bolts. These bolts are pivoted at such distances apart that when turned down to lie between the disks the point of one shall just reach and rest upon the base of the other, thus economizing space and preventing choking or clogging by the beaters. At the rear of the mortar, the bottom and bed are curved, and the peripheries of the disks move close to them, and at the other end of said mortar sufficient space is left to allow the beaters to be thrown out horizontally to strike the die. Screens are provided, so the pulp passes out of the mortar when crushed fine enough by the beaters. The disks are revolved towards the hopper, and each beater, after it passes the center of gravity, falls forward and downward from its place between the disks, and strikes its blow on the rock on the die. The continued revolutions of the disks then draws the beater backward over the die, grinding and pulverizing the ore it has broken. This action is repeated by each beater.

The rate of revolutions of the disks determines the force and rapidity of the blows, the latter increasing with the speed as the centrifugal force becomes greater. The blow delivered upon and the subsequent dragging of the beater over the rock have a beneficial effect in thoroughly disintegrating and reducing it to a fine pulp. Any of the beaters may be removed and replaced when desired.

Timbering in Mines, No. 10.

Fig. 1 of the accompanying engraving indicates the arrangement of timbers and supports by which vertical pieces can be made to serve as supports.

Fig. 2 represents the temporary timber framing for circular sections on the French system. These frames are placed a short distance apart, supporting the facing boards, and are rendered solid by the cross timbering. Slips are also nailed or pinned to and on the support. These methods may be used according to the nature of the ground being mined. The engravings are sufficiently clear in themselves and need no detailed description.

CALIFORNIA RAILWAY APPLIANCES.—California will be represented at the coming exposition at Chicago of railway appliances. General Master Mechanic A. J. Stevens, of Sacramento, has sent a model of his new improved valve motion for locomotives. By this invention, the eccentrics, links and all the appurtenances usually placed between the frame of the locomotive and under the boiler are entirely done away with. The merit of the invention is, that steam can be cut off at any point of the stroke and retain the cylinder full of steam to the extreme end of the stroke. This, it is believed, effects a saving of thirty-three and a third per cent. of steam, and, consequently, also of fuel. Mr. Stevens has also sent drawings of the new mammoth locomotive that is being constructed at the Sacramento shops, and to be named El Gobernador (The Governor). This engine will be much larger than the one in use at Tehachapi, which is at present the largest in the world. The exposition opened on the 24th instant, and will close on the 23d of June.

118 and 120 Market Street, and 15 and 17
 California St., San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoriafers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods both as to quality and price. Our New Illustrated Catalogue, with prices, will be sent on application.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application. Agents for the Patent Plumbago Crucible Co., London, England.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

CUT-OFF FOR SCREENING DEVICES FOR MIDDINGS, FLOUR, ETC.—George Cottrell, S. F., Cal. No. 277,547. May 15, 1883. This invention relates to a new and useful cut-off to be used in connection with purifiers, reels, centrifugal machines and other screening devices for separating the different grades of middlings, flour, etc. In machines for this purpose, whatever may be their character, the material is sifted through the cloth sieve, reel, or other screening device to separate the good from the poor. The good passes through and is directed down to suitable screw-conveyors, by which it is carried off. In this operation, when the material first passes upon or into the screening device, it lies in such quantities that none but the good stuff can pass through, but as it reaches the farther end and becomes thinned out the poor material works its way through also, to some extent. It has been the practice heretofore to arrange under the screening device slides, or what are usually called "flop-boards," which, as their name implies, are flat boards, which can be turned from one inclination to another to direct the material into one or the other of two conveyors. When it is found that at a certain point in the screening device the material comes through, poor with good, then a flop-board at that point is turned so as to direct the stuff into a separate conveyor, from which it is taken and passed through again. The objection to the slides is that they are inconvenient, and the fault with the flop-board is that they do not fit closely enough to form tight joints. The object of this invention is to provide an improved means for accomplishing a perfect result; and it consists in a number of spouts or clutes hinged upon the center board separating the conveyors and having semi-circular sides adapted to fit in slots or grooves made in the under portions of the separating partitions, secured between the walls of the hopper or gather-boards above. The spouts are thus made to form close joints with each other, and may swing from one inclination to the other without allowing any material which falls into one to get into the other.

APPARATUS FOR MATURING SHERRY WINE.—Mannuel T. De Abreu, St. Helena, Cal. No. 277,554. May 15, 1883. This invention relates to an apparatus for maturing sherry wine; and it consists in a novel construction and combination of parts. In the maturing of sherry wine it is customary to expose the casks or tanks containing it to a long continued heat, and for this purpose they are usually placed in buildings or chambers which may be closed tight. Within these buildings the tanks or casks are subjected to the action of hot air from furnaces or heaters until the desired change is effected. Great care must be exercised not to let the heat become too great, and also to prevent fires, and in any event the casks become dry and must be re-coopered, and a considerable percentage of the wine is lost by evaporation. In this invention there is a house or chamber to receive tanks or casks and above it is a glazed structure, one opening into the other. The heat of the sun is intensified and retained so a high temperature is allowed. The heat produced in the upper glazed structure circulates freely in the lower one, and sherry wine is thus matured with very little artificial heat. Heating pipes are arranged for night and cold or cloudy weather.

RAILWAY SWITCH.—Thomas J. Daly, S. F., Cal. No. 277,552. Dated May 15, 1883. This

invention relates to railway switches of that class in which an arm or device attached to the car is adapted to come in contact with and operate a lever in the road-bed to throw the switch. It consists in the construction of a peculiar arm attached to the car, and in the novel arrangement and construction of the actuating lever in the road-bed, together with a swinging cover to protect it. The object of this invention is to provide an automatic switch especially adapted for street railways. By reason of its construction, the switch rail will remain normally closed, but will be thrown in readiness for the front wheel, and will thereafter be controlled by said wheel, and by the arm upon the car until the rear wheel takes charge of it, which it will close again for the straight track.

WRENCH.—Joseph McAlpin, San Francisco, Cal. No. 277,590. May 15, 1883. This invention relates to a new and useful wrench; and it consists in suitable jaws fitted one upon the other, to move together or apart, and in a handle connected with one jaw by a knuckle-joint, and with the screw-shank of the other by a loosely seated or swiveled ball-nut, whereby said jaws may be adjusted by the nut and their grip tightened by the power applied to the pivoted handle. The object of this invention is to furnish a wrench having not only the ordinary power of gripping, but one whose grip is increased in proportion to the power applied to operate it to avoid slipping, and further, to provide a wrench which may be readily used in small space with facility and with great power.

FOUNTAIN.—Maurice M. Murray, Coulterville, Cal., assignor of one half to Alexander G. Black, of same place. No. 277,598. May 15, 1883. This invention relates to an improved vessel for containing liquids and keeping them cool or warm, as may be desirable. It consists in an outer vessel having a pivot adapted to revolve in a step of a base, and provided with interior divisions for various liquids, in combination with a removable cover, through which a series of funnels project, and carrying on their lower ends the stoppers of the interior vessels, whereby the inventor is enabled to fill all the interior vessels and main vessels without removing the cover.

HAY RAKE AND LOADER.—Ebeuezer B. Towl, Franktown, Nev. No. 277,174. Dated May 8, 1883. This hay loader consists in a wheeled frame, adapted to be attached behind a wagon, and provided with a peculiar directing apron in which a novel toothed cylinder revolves, and from which a traveling draper extends to the wagon, whereby the hay is picked up by the cylinder, elevated to the draper and by it carried to the wagon. The object is to provide a simple and effective machine to load hay upon a wagon to which it is attached, and which it follows.

CANISTER.—Clarence M. Symonds, San Francisco, Cal., assignor to George H. Tay & Co., of same place. No. 277,630. May 15, 1883. This invention relates to an improvement in canisters, such as are usually employed to contain tea, coffee or spices—and in an open and pivoted closing slide upon the top.

News in Brief.

BISMARCK is framing a plan of an Imperial insurance department, the duties of which will be to supervise insurance companies in Germany.

THERE were twenty-two deaths from yellow fever during the past week at Cuba, mostly in the military hospital.

THE cost of the Brooklyn, N. Y., bridge, so far, has been \$14,627,379.69. The cash on hand is \$62,526.14, and the liabilities are \$146,166.45.

THE City of Peking, on her next trip from Hongkong, will bring about 400 Chinese passengers, coming back to San Francisco on their return certificates.

CHINESE are being smuggled into Washington Territory from British Columbia. Fight are reported to have been murdered by Indians who were rowing them across.

MANY Americans have left Paris for Moscow, among them Mr. Mackey of the Comstock, who makes the journey with his family in his own palace car, in a style that creates great astonishment.

FROM advices received from points in Illinois visited by the cyclone Friday night, 63 deaths have already been reported in the State, and the number of injured is estimated at very nearly 200.

THE five sea elephants which left San Francisco on the 11th instant, arrived in New York on Saturday evening. Two of them will, in a few weeks, be sent to the London Zoological Garden, and the others to the Jardin des Plantes, Paris.

THE other day the Portland, Me., dry dock was opened for a vessel to come in, and after the gates were closed and the water pumped out, it was found that a large school of herring had been captured.

THE mineral exhibit at the Denver Exposition grows in magnitude every day. The counties in Colorado, under the State law, have thus far appropriated \$50,000 for the mineral collection.

CONTAINING all the essentials of a true tonic, and sure to give satisfaction, is Brown's Iron Bitters.

English Investments in the Pacific Coast Mines—No. 5.

[Prepared for the MINING AND SCIENTIFIC PRESS by H. DEGROOT.]

The Utah Silver Mining Company (Limited).

Another London incorporation, with a capital stock of £100,000—10,000 shares of £10 each—purchased in 1872 from Buel & Bateman a group of mines in Bingham Canyon, consisting of the Red Warrior, Dartmouth, Portland, Belshazer, and one or two others, paying, as usual, an unduly large price for the same, none of these so-called showing at the time much good ore or being much developed. Two smelting furnaces having a joint capacity of thirty tons per day were soon after erected near the claims, and run for a year or two with but moderate results. The ores of this company, like the most of those in the Bingham district, ran low in silver though rich in lead; the bullion made here being worth but \$125 per ton—the poorest produced in Utah Territory. Below the oxidized zone the ores grew base, iron as sulphuretted becoming very pronounced. This change in the character of the ores necessitating their being dressed before going to the smelters, the company put up costly works for that purpose; shortly after these dressing works had been completed the ores underwent still another transformation, changing suddenly to an almost solid zinc blend, and becoming so poor in galena as well as silver, that they could no longer be worked with profit. As a result the company was obliged to give up working their mines, though the dressing machinery continued to do some custom work for a while longer. But the earnings from this source being insufficient to keep life in the concern, operations of all kinds were finally suspended. No dividends were ever paid by the company, and, except a trifle realized from the sale of their plant, the money invested proved a total loss.

Mammoth Copperopolis.

This mine is located in the Tintic mining district, Juab county, and about 75 miles southwest of Salt Lake City. It is on the same vein as the Crismon-Mammoth, a mine that for many years has enjoyed an excellent reputation, and which it adjoins on the south. The vein is a very large one, and carries ores rich in gold, silver and copper. In one of the excavations made on this lode it presented the remarkable feature of a stratum of rich auriferous quartz lying by the side of a 12-foot vein of copper ore, the former constituting the foot-wall of the latter.

The mine was sold to an English company in 1871, who at once erected a ten-stamp mill for reducing the free gold-bearing ores, and also two furnaces for smelting the copper and silver ores. The gangue in this lode consists mainly of a granulated quartz, carrying besides gold and silver a large percentage of copper carbonates, oxide of iron, zinc blende, bismuth and a small quantity of lead. The mine has been well prospected and somewhat developed by means of several large surface openings and by tunnels, one of which intersects the lode at a depth of 200 feet; a shaft has also been sunk on the lode to a depth of sixty feet. From these openings large quantities of high grade ore were extracted in 1872 and shipped to Liverpool. The first class ores here run about thirty-five per cent of copper, fifty ounces in silver and usually a little gold, some of the ore being very rich in that metal. While the English company, after the custom in those days, paid a great deal too much for this property, the investment, had the enterprise been well managed, might still have proved a good one. But the business at the mine seems to have been badly conducted, costly plant, both a mill and furnace having been put up in advance of ore development, and much money wasted in road building and other improvements not strictly necessary. In locating the reduction works the blunder was made of placing them at a point where it was impossible to get enough water to keep up steam more than a few months in the year. Struggling along for a few years without making any net earnings or even defraying current expenses, the company became embarrassed and finally suspended operations, the most of the money invested in the enterprise being lost.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First St., a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. Reference as to above can be had upon applying to this office.

Complimentary Sample Copies of this paper are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage; and as far as practicable aid in circulating the journal and making its value more widely known to others and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year.

N. B.—Personal attention will be called to this (as well as other notices, at times), by turning down a leaf. Extra copies mailed for 10 cents, if ordered soon enough.

PRIZES AT THE SACKETT SCHOOL.—Sackett School closed on Friday with the following award of medals and prizes: The "Hathaway" gold medal, offered by Jotham Bixby, Esq., of Los Angeles, for excellence in the study of classics, to Charles C. Stevenson, of Idaho City, Idaho Territory, with honorable mention to Richard Belcher, of Marysville. The Harmon gold medal, offered by A. K. P. Harmon, Esq., of Oakland, for excellence in the study of the English language, to James A. Crawford, of Los Angeles, a graduate in the English course of study. The second cash prize of \$5 to Frank White, of Penryn. The Haines prize of \$10, offered by J. W. Haines, of Nevada, for gentlemanly conduct in family, to Frank White, of Penryn. The prize for improvement in writing, to Master Alex. McDonald, of Oakland, with honorable mention to Frank Owen, George Brown and Harry Burdick. Prizes in spelling, to Henry Myers, of Courtland, and Henry Chauvet, of Glen Ellen, with honorable mention to Robert M. Dodsworth, of Los Angeles, on the classical course. Honorable mention was made of J. Tully, of St. Helena, Benj. Brierly, of Point Gamble, W. T., and Charles Adecock, of San Francisco. The term has been one of unusual earnestness and fidelity in study. J. M. McPherson, A. M., Professor of Mathematics in Fish University, has accepted the position of head master and teacher of mathematics in the school. He will enter upon his duties July 16th.

APPRECIATIVE.—THE MINING AND SCIENTIFIC PRESS published by Dewey & Co., of San Francisco, is one of the most valued of our exchanges. Whenever we find it on our table we naturally reach for the scissors, knowing from past experience that every fresh number contains something of general interest in any community. The last issue, containing double the amount of reading matter, was especially devoted to Arizona and its mines. In this connection we note with pleasure that Mohave county is beginning to attract that attention among mining journals which it has long deserved, but has heretofore been denied.—*Mohave County Miner*.

JUDGES AND MINERS.—The Tombstone Republican says: It is peculiarly unfortunate for people living in sections where the principal industry is mining, and where more or less litigation is constantly in progress, that judges should be sent them who, by their own admission, are totally ignorant of all law bearing upon mining cases, and wholly incompetent to render intelligent decisions. As a natural consequence, valuable mining properties are tied up, and the whole community is forced to suffer through the incapacity, or fear, of a federal judge to venture even so much as an opinion. How long, oh! how long! are we to be thus afflicted?

Our Agents

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. MCGRAW—Santa Clara county.
 M. P. OWEN—Santa Cruz county.
 J. W. A. WRIGHT—Merced, Tulare and Kern counties.
 JARVIS C. HOAG—California.
 B. W. CROWELL—Arizona Territory.
 N. H. HAFORD—Plumas county.
 M. H. JOSEPH—Eureka, Nev.
 F. W. STRATTON—Placer, Nevada and El Dorado counties.
 J. M. LEBRY—Los Angeles, San Bernardino and San Diego counties.
 A. C. KNOX—Oregon and Washington Ter.
 M. D. SHRAEDER—San Mateo county.

ORE PULVERIZER.—The rotary ore pulverizer, advertised in another column as for sale by Mr. Heald, has been used but very slightly, and is a bargain to any one in want of such a machine. It is only sold because the company which ordered it is dissolved, and there is no possible use for it. All the necessary gearing, frame, etc., go with the pulverizer, which can be set running in half an hour after it is received. Parties needing something which will grind ore fine, will do well to communicate with Mr. Heald concerning this machine.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

ROCK DRILLS. "CLAYTON" IMPROVED MINING PUMPS. AIR COMPRESSORS. For CATALOGUES, ESTIMATES, Etc. Address, CLAYTON STEAM PUMP WORKS 45 & 47 York St., BROOKLYN, N.Y. (Near Approach to New York & Brooklyn Bridge.)

OTTOKAR HOFMANN, Metallurgist and Mining Engineer.

Erection of Leaching and Chlorination Works a specialty. Address,

Cor. Fifth and Bryant Sts., SAN FRANCISCO, CAL.

Exploration of Mines After Accidents.

In last weeks Press we had something to say on this subject and now copy the following from *Iron*: Mr. W. Howard, of Chesterfield, the secretary of the Chesterfield and Derbyshire Institute of Mining, Civil, and Mechanical Engineers, referring to the circular addressed by the Home Office to owners of coal mines and others interested in coal mine operations throughout the kingdom, states, in a letter to the *Times*, that the government recommendation of "the creation in mining districts of stations where the Fless apparatus should be stored in sufficient numbers and maintained in readiness for immediate use, and where the instructions for men from the surrounding coal mines in its use should be systematically carried out," was brought before a meeting of the Chesterfield and Derbyshire Institute of Mining, Civil, and Mechanical Engineers on April 14, by Mr. Jackson, the managing partner of the Clay Cross Collieries, and that the required organization will be at once taken in hand under the auspices of that institute. Mr. Howard adds: "It is satisfactory to be able to add that the first use of the Fless apparatus in a coal mine was at Netherseal Colliery in this (the Midland) district, in the beginning of 1881, its use on a more extensive scale at the Seabam Colliery being later, viz., in June 1881, and at Killingworth Colliery in April 1882. It is probable that the organization of the St. John Ambulance classes, first taken up, in connection with mining, by the same institute, and now in operation here at most of the collieries, may be extended to training in the use of the Fless apparatus. Another invention (Libin's firelamp and escaped gas indicator) has within the past fortnight and for the first time in this country been subjected to trial at Chesterfield by myself, in concert with Mr. C. E. Jones, of the Chesterfield Gasworks. The trials extended over three days, and were in part witnessed by the chief and assistant government inspectors of mines for the district and about twenty managers of the leading collieries, including Staveley, Clay Cross, Eastwood, Blackwell, Sheepbridge, Riddings, Pinxton, Unstone, Boythorpe, Albert, Alma, Pilsley, and Tinsley Park. The result showed that, compared with the Davy safety lamp—still almost universally used in searching for firedamp in mines—the Libin indicator denotes a less percentage either of manufactured gas or of firedamp than the lamp. This was proved first by exact and thoroughly diffused mixtures of ordinary lighting gas with air, three per cent scarcely showing in the lamp, but being indicated with perfect distinctness by the Libin instrument, at two per cent similar mixture being also indicated by the latter only. On further trial in a coal mine at Boythorpe, the lamp showed firedamp in one only of three places, in all of which the Libin instrument indicated its presence. The instrument as used in the mine on this occasion was connected with a small electric battery carried in a waist belt, and connected by wires with a bell; by a sliding contact arrangement no spark was given off. In this form it can be employed for examining any place in a mine that can be examined with a safety lamp. For positions in which it can be permanently fixed, it is designed to communicate and keep up intelligence of the state of the main return airways to the manager's office. In both forms, fixed and portable, but chiefly in the former, there are wide fields for its use elsewhere than in mines, particularly for the detection of gas in coal bunkers on board ship, and in buildings. On board ship, especially, at different points among the cargo, where safety lamps cannot be introduced, the automatic registration of several Libin's detectors, each having a separate wire and indicator, and employed either separately or together with similarly equipped thermometers, would denote the place, degree, and extent of danger. Such warnings would, of course, suggest means of remedy in each particular instance, and ultimately, it may be expected, would lead to better methods of stowing and ensured safety."

BAKER'S MINING HORSE POWER HOIST.—When a man first begins to open up his claim an ordinary hand windlass does very well. But, when he gets down fifty feet or so he begins to think he has a pretty good job on hand, hoisting by hand, and looks about him for some better means. Steam is too expensive and the ordinary horse whim too clumsy and bothersome—an appliance which in its crudity is more trouble than it is worth. An efficient and practical machine is now made by the Pacific Iron Works, of San Francisco, and at their branch works in Chicago, which just fits in this period of development of the mine. This is the "Baker Mining Horse Power Hoist." The machine is strong and simple so that any one can manage it, and a horse does the work. The following are some of its advantages: It is made entirely of iron, and is, therefore, very durable and not affected by climatic changes; no piece weighs more than 250 pounds, thus admitting of its being packed on mules to otherwise inaccessible localities; the hoisting drum is under the complete control of the man at the shaft, and is capable of carrying 500 feet of five-eighths steel rope; a pulley may be placed upon the end of the drum in such a way that a pump can be run continuously without interfering with the hoist; at the ordinary speed of a horse a thousand-pound bucket of ore can be raised at the rate of 120 feet per minute; the cost of erection is slight, as two men in half a day are able to put it in place ready for work.

One Guilty Man Who did not Escape.

We wish to put it upon record as prominently as possible, that one man who proved recalcitrant to a public trust and plundered the public treasury, has received his deserts at the hands of a court of justice. So many thieves have escaped, so many plunderers have failed of punishment, that people have almost despaired of justice, and criminals have looked upon large stealings as eminently safe spoils. That a decision has been reached, and a sentence passed which consigns a public plunderer to a common criminal's cell is a matter for general satisfaction. It will have a most wholesome effect upon the behavior of other men in places of trust; it will spread the impression that honesty in office is as necessary as honesty in private life, and that dishonesty is just as dangerous.

To show that we have a judge who can take an old-fashioned view of official corruption and that there are most cogent reasons for severity with public offenders, we give below the address of Judge Crane, of the Alameda County Superior Court, in pronouncing a sentence of fourteen years in the State prison against Kay, the county treasury thief. He said:

Maro P. Kay, you have been convicted by your own confession of guilty of the crime of forgery. The forgery consists in forging a county warrant for a not very large amount, it is true—\$76. This crime has always been looked upon in law as one of the most dangerous that could be committed against the peace and good order of society. It strikes at the foundation of all confidence between man and man, and destroys all confidence in the integrity of public officials. In addition to having committed the simple crime of forgery—which, under the English law, and until a late period, was punishable with death—you have added to it the enormous offense of betraying a sacred trust. Among all your fellow-clerks you were selected as the Deputy Auditor of this county. As such you held the keys to the treasury, and were authorized to draw orders in the name of your principal, on the county treasury for any sums for which they might properly be drawn. This trust you have basely betrayed. It has not even the excuse of a crime that has been committed under circumstances of temptation, or in the heat of passion, or under an excitement, or under the pressure of want. So far as it appears, you were amply provided for, so far as salary was concerned. You had no need of this money for any legitimate purpose. Indeed, there has been no circumstances of extenuation shown to the Court. It is simply, barely and only the fact that you were the trusted, confidential deputy of your principal, and that you deliberately, and without any apparent motive or cause, other than the commission of crime for your own gain, have committed this forgery for which you have been arraigned, and of which you have pleaded guilty. Now, while the object of the law is reformatory so far as the criminal is concerned, it has another object in view, and that is, that justice shall be dealt out to those who offend. This justice must be in proportion to the enormity of the offense and must be such as to deter others who may be disposed to commit a like crime. We can conceive of no possible mitigation in law, looking at the face of this offense. Every portion of it seems stamped with the enormity of crime of the worst guise—of deliberate, preconceived, cool, calculating crime. We do not think, therefore, that in the discharge of our duties, as the guardians of the public peace, and as the administrators of justice, we should be justified in inflicting a light or even a mitigated sentence for a crime of such enormity. If our public officials cannot be trusted, if those who are placed in places of confidence cannot be relied upon, what reliance is to be placed upon those who are not in such positions? You have not even the excuse of being ill-informed. You are educated—you have greater light than an ordinary criminal has—and therefore are more accountable. Now, under all the circumstances of the case, the Court have come to the conclusion, and we have done it deliberately and in view of vindication of the law and the ministration of justice, that the crime deserves the severest punishment which the law can inflict; and now the painful duty only remains of announcing the conclusion in regard to the sentence, to which the Court has come, and that is that you, for this crime of forgery of which you have pleaded guilty, be confined in the State prison for the term of 14 years.

We trust these weighty words will be duly pondered, and will have due influence both to warn those who may be tempted and to awaken those who are prone to sympathize with dishonest officials to the fact that a sin against the people is really an outrage greater than the coarse deeds of low thieves, and should not be condoned or excused. Let Judge Crane's sentence be also an inspiration to the people; a surety that it is not the true province of the law to prepare for the escape of the large villains and the punishment of the little ones, but that the punishment is to be commensurate with the crime committed or the trust betrayed.

NERVOUSNESS, debility, and exhausted vitality cured by using Brown's Iron Bitters.

SUFFER

no longer from Dyspepsia, Indigestion, want of Appetite, loss of Strength, lack of Energy, Malaria, Intermittent Fevers, &c.

BROWN'S IRON BITTERS never fails to cure all these diseases.

Boston, November 26, 1882.

BROWN CHEMICAL CO.

Gentlemen:—For years I have been a great sufferer from Dyspepsia, and could get no relief (having tried everything which was recommended) until, acting on the advice of a friend, who had been benefited by BROWN'S IRON BITTERS, I tried a bottle, with most surprising results. Previous to taking Brown's Iron Bitters, everything I ate distressed me, and I suffered greatly from a burning sensation in the stomach, which was unbearable. Since taking BROWN'S IRON BITTERS, all my troubles are at an end. Can eat any time without any disagreeable results. I am practically another person. Mrs. W. J. FLYNN, 30 Maverick St., E. Boston.

BROWN'S IRON BITTERS acts like a charm on the digestive organs, removing all dyspeptic symptoms, such as tasting the food, Belching, Heat in the Stomach, Heartburn, etc. The only Iron Preparation that will not blacken the teeth or give headache.

Sold by all Druggists.

Brown Chemical Co.
Baltimore, Md.

See that all Iron Bitters are made by Brown Chemical Co., Baltimore, and have crossed red lines and trademark on wrapper.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Out-off Poppet Valve Engine, and Forced Iron Crank Shafts.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

—OR—
VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

EXCELSIOR BLASTING POWDER,

Manufactured by the

EXCELSIOR POWDER COMPANY.

This is no new, patent, non-explosive Safety Powder, but the Genuine Standard Nitro-Glycerine Powder, as safe to use and handle as any other Nitro-Glycerine Powder manufactured. The fumes and gases, common in nitro-glycerine powders, are destroyed, and do not leave the miner with headache or nausea.

The powder is put up in cartridges of any size to suit the consumer, and is exploded in the same manner as all other high explosives; that is, by means of cap and fuse, or by electricity. It is not claimed for this powder that it is a non-explosive, or safer than other nitro-glycerine powder. All powder, and especially nitro-glycerine powder, should be handled carefully. The EXCELSIOR POWDER is as safe, and for strength far surpasses any other powder on the market. Address all orders to

Improved Postal Scale.

We present on this page drawings of an improvement on postal scales, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, which embraces some new and novel features designed to expedite the operation of weighing letters and other mailable matter. This is done by the apparatus instantly showing the number and value of rates or stamps required for any particular letter, package or parcel, dispensing with all manipulation of the poise and beam, and all computation in connection with the weight, number and aggregate value of the stamps. It will be seen from the drawing that the operation for determining the number of rates, or stamps, and their value at two, three, five and six cents, is by means of two stationary curved rests carrying, on their concave edge, graded weights and two movable curved arms, having the fulcrum, or knife edge, at the point of contact of the two sets of curves, carrying the weight pan upon which the letter or other object is placed, on which the postage is to be ascertained.

The object being placed upon the pan will depress it, and at the same time raise the arms, which successively, on their convex edge, lift the weights off the rest, through the curved slot, until an equilibrium is reached, when the hand, or pointer, attached to the arms will indicate on the index scale, the number of rates or stamps required. These numbers are found in the first series of spaces below the hand, the value of which at two, three, five and six cents will be found in the first, second, third and fourth spaces, below each number of rates. In the open space above the numbers are figures showing the weight; as they are not, however, an element in the operation of the machine, they are not embraced in the index and might, with great propriety, be omitted entirely.

When a letter or parcel is carefully placed (not dropped) upon the weight pan, very little, if any, oscillation will result; the hand of the operator should remain in position, after placing the object on the pan, to remove it the moment the index hand, or pointer, indicates the number of rates, etc. Herein consists the great saving of time, and the vast superiority of this scale or machine over all others, which we believe it is destined sooner or later to supersede.

When the machine is at rest the hand points to, or rests on, the second vertical line in the index, which represents one rate, or one-half ounce, and will not move until the weight upon the pan exceeds one-half ounce. If the excess is but slight, the hand will rest between the second and third lines. A small increase will send it on to the third line, where it will rest until the weight upon the pan exceeds two rates, or one ounce. The hand will then pass beyond the third line, and rest between the third and fourth, or on the fourth line, indicating three rates or one and one-half ounces. Under increased weight the hand will move forward, as above described, until it has passed the last vertical line in the index, indicating that the object is in excess of ten rates, or five ounces. The counter poise weight, "No. 1," is then placed in its rest upon the end of the curved arms, which will immediately return to their first position. If the weight on the pan is not in excess of eleven rates, or five and one-half ounces, the hand will remain stationary, and one rate will be added to the last on the index,

and one value at two, three, five or six cents, as the case may be, will be added to the amount in the column under ten rates.

This process of adding the number of rates and value found in the last column to the number and value of rates shown by the hand, continues until the hand passes the last line in the index, indicating that the weight upon the pan is in excess of twenty rates, or ten ounces. Weight "No. 2" will now be substituted for "No. 1," when the same conditions will follow, excepting that twice the number and value

likely to get out of order. A cover extends over the curved rests and arms protecting and preventing any derangement or displacement of the weights.

For general information, a card, furnishing valuable information on postal matters is affixed to each machine. J. Frank Miller, of Oakland, Alameda county, California, is the inventor and patentee. His address is lock box No. 1300, Postoffice, San Francisco.

COPPER. The import of copper into England

MILLER'S IMPROVED POSTAL SCALE.

found in the last column will be added to the number and value shown by the hand.

The entire absence of springs, wires or friction of any kind, and dispensing with all calculations as to number and value of stamps at any ascertained weight, and all manipulation of the poise (which, except when accidentally at the desired point, requires always two, and fre-

quently three or more moves before the weight is determined), insures the utmost accuracy and dispatch. In banking houses, insurance offices, counting houses, etc., etc., where large numbers of various sized letters, parcels, etc., are daily prepared for the mail, the machine will be of great convenience and value.

In the various post offices, where large numbers of letters, etc., have to be weighed, or tested, it will be invaluable, as it will decrease the time and labor of weighing from eighty to ninety per cent.

For mail matter, other than letters, the machine is graded at ounce rates, with corresponding values, and can, like those for letters, be made of any desired capacity. The machines are not complicated and are comparatively inexpensive.

The machine is in compact form and not

likely to get out of order. A cover extends over the curved rests and arms protecting and preventing any derangement or displacement of the weights.

For general information, a card, furnishing valuable information on postal matters is affixed to each machine. J. Frank Miller, of Oakland, Alameda county, California, is the inventor and patentee. His address is lock box No. 1300, Postoffice, San Francisco.

ANTIMONY is selling in England at £39 and £41 per ton for French Star regulus,

Firedamp and Gas Indicator.

Among the improved scientific instruments for mines, recently put in use, we lately described the Flens apparatus for going into mines where bad air or gas exists, giving the result of some experiments in that direction. Another invention has just been subjected to trial by Messrs. W. F. Howard and C. E. Jones, of Chesterfield, England. This is Libin's firedamp and escaped gas indicator. The trials extended over three days and were witnessed by the Chief and Assistant Government Inspectors of Mines for the district, and about twenty managers of leading collieries. The result showed that, compared with the Davy safety lamp, still almost universally used in searching for firedamp in mines, the Libin indicator denotes a less percentage, either of manufactured gas or of firedamp, than the lamp. This was proved first by exact and thoroughly diffused mixtures of ordinary lighting gas with air, three per cent scarcely showing in the lamp, but being indicated with perfect distinctness by the Libin instrument; a two per cent similar mixture being also indicated by the latter only. On further trial in a coal mine at Boythorpe, the lamp showed firedamp in one only of three places, in all of which the Libin instrument indicated its presence. The instrument, as used in the mine on this occasion, was connected with a small electric battery carried in a waist belt, and connected by wires with a bell; by a sliding contact arrangement no spark was given off. In this form it can be employed for examining any place in a mine that can be examined with a safety lamp. For positions in which it can be permanently fixed, it is designed to communicate and keep up intelligence of the state of the main return airways to the manager's office. In both forms, fixed and portable, but chiefly in the former, there are wide fields for its use elsewhere than in mines, particularly for the detection of gas in coal bunkers on board ship, and in buildings.

German Iron for Bridge Building.

The German iron works seem to furnish the best material for bridges. It is true that the prices of the German works are a little higher, but the quality is so much better that this makes no difference. The superior quality of the German material lies principally in the execution of labor, in the great exactitude of the work, and in the superior quality of material employed. In consequence, accidents like the destruction of the Tay Bridge (which call forth but little comment from the English iron papers) do not happen in Germany. The difference in the working itself is that in Germany all rivet holes are bored, but in England and America they are stamped with a stamping machine, and this method does great harm to plates, very often leaving little vents, and by experience plates are weakened 10 per cent., sometimes even 40 per cent more than by the other method. As regards the quality of the English material itself, it is very well known that it breaks if worked in a cold state. Consequently, at collisions of steamers, when the plates only ought to get bent, they are broken in, and many people lose their lives. Very often German shipowners have been reproached that they have their steamers built in foreign countries notwithstanding the fact that the German iron and steel industry can compete with that of any other country, and has the largest exportation after England. The collision of the *Cimbria* ought to be a warning not to risk valuable cargoes by saving a small amount in cost of steamers, hesitatingly rendering the lives of those, on board more secure.

WEIGHT FOR POSTAL SCALE.

CORRESPONDENCE.

Arizona Notes.

(Written for the Press by B. W. CROWELL.)

Phoenix—Salt River Valley.

This is a thriving little town of about 3,000 inhabitants, the county seat of Maricopa county, which is often called the agricultural county of the Territory. In this matter I cannot speak advisedly, as I have seen but few counties, yet as far as I have seen this compares very favorably in its apparent possibilities. Phoenix is the queen city of the valley, situated 28 miles north of Maricopa station, S. P. R. R., on the direct thoroughfare to Prescott, the capital of the Territory—124 miles north—and has the patronage of an immense freighting business, branching off in all directions from here to the various mines and cattle ranges in the distant hills. The plan of the city is thoroughly American, regular, with wide streets 100 feet for the main avenues, and 80 feet for cross streets. Every street is supplied with a clear stream on each side, running along the curb stone, and so perfect is the natural grading of the plane that it seems almost optional with the citizen which way the water shall flow.

The town was laid out in 1870, and without the aid of any manufacturing establishments except flouring mills, and no near mines or any exciting booms of speculation, it has steadily built up its present large and substantial position, as a permanent town of 3,000 population, with a full beginning for first-class American institutions. There are four churches, a large two-story brick public school edifice for the departments of graded schools, which shows the ruling vote of the community on the subject of education.

The two daily papers, with their weeklies and also another weekly published in Spanish, are somewhat indicative of the intelligence of the people of this valley. Another daily is talked as about to start, showing the confidence another editor has of the future of this town.

The population of the town is perhaps one third Spanish, but they are of the quiet, industrious class of good citizens. The county will erect its permanent public buildings here, this year, on an ample plaza provided for, in the town plot. This, with a large storehouse now building, and other improvements going on, will add materially to the town's appearance, and to the life of business here this year. But there seems to be no desire to build up the town rapidly. The large store firms now doing a thriving business care not to see any large competition come in. The banking firm of Sol. Lewis and M. W. Kales are satisfied if they can enjoy the local business as a unit. This firm lately accommodated the Territory of Arizona by purchasing her bonds of seven per cent, \$260,000, giving a premium of \$12,000 for the same.

The various mechanics seem to be well represented, and having abundance of work at remunerative prices. The main dependence of the city of Phoenix is the rich farming lands of Salt River Valley.

This valley, usually called Salt river, though it joins on and embraces a portion of rich lands, watered by the Gila, is a very extensive plain, 60 miles long by 12 to 20 miles in width. The Salt river has furnished water for numerous ditches for irrigating portions of these lands for cultivation; but still the cry is more water for irrigation, and this demand is being heeded by new ditch enterprises.

Those in the extreme west of this valley are now looking anxiously for the completion of Webb ditch, taking water from the Gila, to excellent government lands. But nearer Phoenix, about 25 miles below the city, work is now being done on another Gila river canal, under the direction of Hon. Mr. Rumburg, that will supply irrigation for miles of rich farming and grain lands on the north side of the Gila, below where Salt river joins with it. There are various natural advantages here for a large colony settlement. The land, rich and choice, with abundance of fuel on the lands, and a large amount of heavy cottonwood timber along the banks of the river. The lands are very easily cleared and easy to cultivate—a rich alluvial sand and gravel, and occasionally some little mixture of adobe. The land is now covered by arrow, sage, or grease bushes, and mesquit hard wood. Right here in this lower portion of the valley are undeveloped resources, ample to build up a good county. When I visited there a few weeks since, there were no signs of any ownership, other than United States government, their survey stakes only appearing.

The lands now occupied in the vicinity of the Phoenix and for twelve miles west and four miles north, are well watered by Salt river ditches, the river passing about two miles south of town, and the Grand canal, about four miles to the west of Phoenix. The lands lying beyond the canal could not be irrigated as they slope all toward the river for several miles. How to reach the vast table lands beyond, has been the problem, and has at last begun to be solved by

The Arizona Canal Co.

Incorporated here in Phoenix, Dec. 20, 1882, by M. W. Kales, W. A. Hancock and Chas. Churchill, with a capital stock of \$500,000, of par value \$500 each share. Work is now being

commenced, by about twenty teams and a force of men under W. J. Murphy, which after the hot harvest season is past will be increased to 100 or more teams, and as many men as are requisite to ensure an early completion for crops in 1885. The present camp will be located near the mouth of the Verde. The capacity mentioned is 40,000 inches, miners' measure. They tap the Salt river on the north bank about three fourths of a mile below where the Verde river flows into it, and where a hard bed rock bottom prevents the sinking of the waters into the sand, at a point about two miles east of Mt. McDowell, thus securing an elevation sufficient to reach the higher mesa lands and irrigate the vast tract to the north and west, not accessible by the Grand canal or other ditches.

Government Land.

It is a good place for a poor man to get a good farm on government lands. The public land is here surveyed and accessible—open plains that with wagon and horses you can drive to any portion of it, and where it is settled and cultivated there are section roads. The light bushes are easily cleared off by grubbing hoe at the rate of one to two acres per day, but with sagebrush rake and six horses they can be cleared much faster. The land is very free and easily cultivated. The merchants seem to have great faith in the cultivator of the soil, and fill their big ledgers with accounts that are to be paid after harvest. I noticed one of these bills yesterday where syrup was charged \$1.75 per gallon, bacon twenty-five cents per pound, flour \$5 per hundred pounds, and it has now advanced to \$5.50. These are high prices, but the farmer soon takes the benefit of these high prices when he sells much and buys little. The house can be built cheaply of the adobe style, with log rafters, brush and dirt and plaster roofs, that will serve till able to do better.

The Settlers from Utah

That come to this territory seem to be very poor, yet they generally have good teams and wagons and some few implements and seeds with them. They will stop and camp, or live in the wagon until they plow and put in some seeds for the first season's use, before they attempt to build any house. In a few weeks they have garden sauce of their own raising, and thus early strengthen their faith in the productivity of the soil. They fully appreciate the importance of useful occupations for all members of the family. For cash to supply needed groceries they will do some work with team, or as laborer in the adjoining settlement, and in a short time, they are all comfortably fixed, with a place of their own.

Phoenix, May 9th, 1883.

Wyoming Mines.

The mines of South Pass, Wyoming, are looking well, and give fair promise of making good showing this season in bullion product. The Carrissa property, owned by B. Rohers and H. S. Reedall of this city, has just been leased to W. W. Pitkin and Nat. Gishorn, the lease having been perfected yesterday. The mine has a large body of \$15 free milling gold ore in sight, and the lessees are in hopes that as depth is gained the ore will improve. Belonging to the property is a five-stamp gold mill, operated by water power. This mill can be doubled in capacity, the water wheel and quantity of water being ample for this, and it will probably be done. This mill is located only half a mile from the mine, hence the cost of getting ore to the mill and reducing is small, and can be further reduced by putting in more stamps, which will require no more hands to operate. Pitkin and Gishorn own the Red Jacket, lying near, on which they have done considerable work, first by sinking a shaft which tapped good ore, and at the same time struck water which drove them out. The property is so situated as to be easily drained by a tunnel. Abandoning work at the shaft, they have driven a tunnel 400 feet, and expect soon to cut the vein at a depth which will free the mine of water and give them a large ore body above. Mr. Pitkin who has been on the property a long time, and is very familiar with mines, is sanguine over the present outlook of that district, which he unhesitatingly pronounces a good mineral region. He says all that is wanted is capital and enterprise to bring the South Pass country into prominence as a gold producer.—Salt Lake Tribune.

There are at present about thirty men working in the Drum Lammun mine running cross-cuts, and sinking three inclines or winzes on the lead about ninety feet apart. The 1,100 feet tunnel is being vigorously pushed into the hill, the men working eight hour shifts. It is reported that the new mill will be erected near the tunnel. Experiments are being made on the ore by running it through the old mill in the process, a drying furnace having been improvised for that purpose. Credit is due to Mr. Cruse in developing this valuable property which is mammoth. Mr. Attwood has purchased a cozy residence and erected offices for the Montana Mining Co., of which he is the superintendent, at the foot of Cruse Mountain which has a back-ground 780 feet high and is highly picturesque.

The Christy Mill and Mining Company of Utah is credited with a bullion product of over \$1,500,000 in the past five years, as follows: 1878, \$302,537; 1879, \$245,466; 1880, \$272,085; 1881, \$316,039; 1882, \$372,426; total, \$1,508,553.

The Deep Spring Country.

Mr. P. A. Chalfant contributes to the *Inyo Independent*, an article on this region of country, from which we condense the following:

The undersigned returned late last week from a brief visit to Deep Spring mining district. This visit was not undertaken for fun, still less with the view of writing an account thereof, but solely as a personal matter, shared by Mr. Oscar Stickney, wherein the moving cause was the hope of finding some clue to the lost key of the great grub question. But, as others, perhaps quite as worthy, are looking for that same clue, it will be well to record a few observations for their benefit. It would fill a book to tell of all the mining claims bordering on Deep Spring valley; their name is legion—though they are all recorded under other names than that.

Numerous as these locations appear to be, they really represent but comparatively few distinctive ledges; as a rule, scarce a ledge but has at least two 1,500 foot claims located upon it, while there are some with not less than six. This is notably the case with one, which, for want of a better known name, is called the

Whiteman Lode.

After "old Gid. Whiteman," one of the most widely known prospectors on the coast, and also one of the original locators of the ledge in question. There are no less than six consecutive locations on this lode, besides two or more on what appears to be a branch of the same. The ledge having a plainly discernible dyke of porphyritic rock for a foot-wall, and cutting across several lateral ravines, runs northeasterly from the valley along the high ridge facing Soldiers' Pass, on its northwestern side.

The deepest of these lateral ravines cuts the ledge near the middle of its length. Scores of assays were had, and scarce one fell short of a hundred dollars to the ton, silver almost exclusively, while a fair proportion went double that, some even to \$600. Some coyote holes, the deepest not exceeding fifteen feet, were sunk on each of the several locations, and quantities of good ore, ranging from a hundred pounds or so to eight or ten tons, were extracted from all of them, the largest pile being found on the branch lode.

Certain it is that the croppings and solid rock near the surface of the vein yet retain their silver in paying quantities, as has been demonstrated time and again. For the most part, if not in its entire length, the vein cuts across the general stratification of the granite country rock. About half a mile north of this Whiteman lode is a parallel ledge, called the Gilbert, which crops out for a distance of about 1,600 feet, the southern end extending quite down into the valley. William Hedge, whose faith in this ledge and the district in general is sufficient to remove mountains, is working away upon it, single-handed and alone. Thus he has managed to get a shaft down some 25 feet. While he does not claim to have "struck it" in the full sense of all that phrase implies, he does find about three feet of ledge matter in the bottom, and interspersed through it, small quantities of rich ore, mostly black or brown oxides, but also considerable Stephanite.

Directly across the valley, on the side of the main Inyo range facing the valley, are to be found numerous claims, some of them having been located and worked twenty years ago, and with which, notably the Ciudadella, are associated some thrilling tales of the subsequent Indian troubles. Not having seen these mines, as well as dozens of others overlooking the valley on all sides, especially the west and north, all that need be said, is that so rich have several of them always shown themselves to be, that some of the very first locators are still at work upon them. The Hiskey and Walker five-stamp mill, erected in 1872, worked several months on gold ores from a number of these ledges, quite a large lot of "Blue Bird" going as high as \$625 per ton, it was claimed that this mill turned out more bullion per stamp than any other ever run in the county, nevertheless, after a few months' operation, the superior attractions of the Lida valley mines, forty miles distant, caused the removal of the mill to that place where it yet stands.

The rather lofty ridge at the north end of the valley is the division between Wynan and Cottonwood creeks, the two being some eight miles apart. The latter debouches into Fish Lake valley.

Some five miles up Cottonwood, from Piper's, and mostly on the northern face of the ridge above alluded to, are to be seen many locations. In general, these ledges are small, but yielding exceedingly rich ores, both gold and silver. This has been the scene of some thirteen years' continuous operations by Mr. O. K. Berry, the Recorder of the district. During all these years Mr. Berry has wrought, often entirely alone, sometimes in *bonanza*, sometimes in *bo-rasco*, (especially in the matter of a sufficiency of "grub"), on different ledges in the vicinity, from which, at intervals, he has shipped enough high grade ore to supply necessities, although it has happened that \$300 ore, in lots of two or three tons, barely paid shipping and reduction expenses.

Among others of Mr. Berry's locations, was one known as the "78." This he had opened in several places; the principal work was just below the summit of a narrow ridge, permitting a tunnel from the east side and a 45° incline from the croppings on the west side.

The ores generally of the district are of a

class susceptible of successful concentration, both silver and gold. It is likely that method (concentrating) will give better results than any "silver process" involving roasting and all that sort of thing. The gold ore can be worked to a pretty high percentage by battery and plates alone, but they, too, should be concentrated. The "78" mine can certainly furnish ore enough to keep a five, perhaps a ten-stamp mill going right along. There are other ledges near by apparently quite as large or larger than this, and so far as opened, no less promising. There are perhaps a hundred dumps within reach of the two creeks named, on each of which paying ore is now piled up. There is an immediate need for a small mill on each of these creeks. With such, and square and liberal dealing, Deep Spring would give profitable employment to a very large number of chloriders, saying nothing of the prospect for deep and permanent mining.

Sampling Mills.

The main business in hand by superintendents Yerington and Laws, of the Carson and Colorado, upon their present visit, is to fix upon the location on their line of two or more sampling mills, where ores can be received, sampled, bought and paid for by ore buyers. Such a "plant," consisting of a steam engine, rock breaker, small pulp mill, assay office, etc., can be established at a cost of \$2,500, and it is probable that three will be needed—at Bishop, Big Pine, or Independence, and near the lake Mr. Wm. B. Miller, superintendent of the Melrose reduction works near Oakland, accompanies the party, and will spend some time in examination of the various districts, mines and character of the ores, in furtherance of the enterprise.

In this our mine owners and prospectors, whose properties have dragged upon their hands as almost worthless, because of the absence of any way of realizing upon the ore extracted, will at once begin to see a gleam of daylight. Many old ore dumps will be cleaned out, realized upon, and new work and actual deep developments begun. The railroad managers are wisely determined that the purchasing agents shall satisfy all ore producers that their sampling is perfectly fair, and that the prices paid, by whatever works wanting the ores, shall be exactly in accordance with their true value in the metals contained. This is accomplished by the seller taking a precisely similar sample and sending it here, to San Francisco or where he pleases to acknowledged experts, for assay and comparison of results.

Now, if we want better times, let those who can and who know they have good ore, get to work and take it out. The cash therefor can be obtained at the most liberal prices consistent with safety to the buyer. These affairs will lead up to the final establishment of some great central reduction works in the valley, capable of handling any kind of our mineral products.—*Inyo Independent*.

The Wood Business of the Truckee Basin.

The wood business of the Truckee basin is no small portion of its source of wealth. As is natural in every country where sawmills abound, and lumber is made, cord wood forms a principal adjunct. Many large trees 50 to 80 feet high arc cut down from which only one good saw log, perhaps 20 feet long, or even less, can be obtained, the remainder being cut up into firewood, and not left to rot on the ground. The Central Pacific, with its large number of engines, consumes vast quantities. Carload after carload is shipped to the valley west and the country east, and piled in their woodsheds for use during the year. Something of an idea of the contribution of the Truckee basin to this demand may be gleaned by knowing that Brown furnished last season 3,000 cords; Prosser creek, 5,000; Martis creek, 6,000; Truckee, 18,000; Donner boom, 4,000; Donner lake side, 3,000; Champion's, 3,000; Kneeland's mill, 3,000—total, 45,000 cords, all of which is purchased by the Central Pacific Railroad Co. The winter of 1881 and 1882 proved a cheap one for the railroad company. The best wood is cut in the fall and winter, for the reason that the bark holds closer to the wood, and the railroad company always tries to contract for wood cut during the fall and winter months. The labor is principally by Chinamen, who receive an average of \$1.50 per cord for cutting, the wood when delivered at the track selling from \$3.75 to \$4 per cord.—*Truckee Republican*.

Some two or three years since, the agents of the C. P. R. R. looked over the coal mine at Gorse Creek, Idaho, and pronounced it good. They gave it as their opinion, that the coal very nearly resembled the celebrated brown coal of Germany. At the present time there is a party of practical miners at work in these mines, sinking shafts and tunneling; and before long it is confidently expected that one of the largest and richest coal beds in the West will be opened up, and added to the already large mining interests of the region.

The Silver City papers are justly proud of the recent strikes made near that place. They are a credit to the country and will be a substantial benefit to the town. Such discoveries cannot fail to bring New Mexico to the attention of the mining world even more prominently than heretofore.

MECHANICAL PROGRESS.

Proper Use of Belting.

The mode of applying belting in transmitted power should always be correct, because there is a great chance of loss in percentage if this is not attended to. The friction between the belt and the pulley is the source from which the power of the belt is derived, and there is a great difference between the sliding friction of the belt and the adhesion of the belt to the pulley. The latter often wastes more power than it serves to transmit, while the former confers the real power, so that in applying rosin, oil, and other adhesive substances, a good deal of power is wasted instead of helping to increase it. It requires power to tear a belt from a sticky pulley, and the amount of force required to do this is so much wasted. The friction between the belt and pulley is the whole source of power, and the coefficient of this friction will be the measure of the power of the belt.

While want of strength would render a belt useless, an increase in the strength would not increase its ability to transmit power unless the friction was increased at the same time. There are certain elements that tend to increase the efficiency in every belt, and others that detract from it. Those that increase the efficiency of every belt are the friction between the belt and the pulley, and the tensile strength of the belt, and those that tend to decrease the efficiency are adhesion; the power required to bend the belt, and the extra friction caused by the tension of the belts on the pulleys. Adhesion is found to exist most perfectly between surfaces that are coated with some semi-liquid, such as castor oil, and the least amount of adhesiveness is found between two dry substances, such as between a dry belt and a dry pulley.

The power required to bend a thick belt is greater than may appear at first sight, hence it would be better, in order to save power, to use a broad thin belt than a narrow thick one, and as it has been found that the resistance of the belt bending is inversely as the diameter of the pulley, it will always be found that large pulleys are the most economical in this respect. Experiment has demonstrated that the greatest effect is obtained when the belts are moistened with water, and the least when moistened with oil. Friction is always in proportion to the pressure, and not the amount of surface in contact; and experiments will show that two belts, one being only half the size of the other, will give an equal amount of power when the pressure is the same, but when the pressure is very slight, an increase of surface may result in an increase of friction. It has been fully proved, however, that where the pressure is excessive any diminution of the surface will cause an increase in the friction.

Compressing Bran.

Mr. Seamans, Secretary of the Millers' National Association, has been authorized to pay an award of \$1,000 to any one who will construct a machine capable of being put to practical use, which will compress 100 pounds of bran into a space equivalent to a fifteen-inch cube, which is equal to 3,375 cubic inches. The object is to bring the refuse of wheat grinding into a form sufficiently compact to make it a transportable article of merchandise.

In reply to this offer, a correspondent of the *Millers' Journal* says, "It can't be done;" to which assertion Mr. Seamans replies as follows:

"The Belt Packing Company, of Minneapolis, will pack one ton of bran in a space 6½ x 2½ x 2½ feet, which is equal to 3,375 cubic inches for 100 pounds. I have a sample in my office made by this machine, which is compressed to the rate of 3,150 cubic inches for 100 pounds. I have another compressed at the rate of 3,075 cubic inches; both are pressed dry. The party producing the latter sample says of his machine: 'My machine will compress 110 pounds in a cube of fifteen inches square, which is more than you require. My machine is very simple, easy to operate, worked by hand or power; is not expensive. Full size, nine feet high, three and a half by two feet on the floor,' etc., etc. I have letters from at least ten parties that claim to be able to fulfill the requirements. A machine is now in operation in Chicago which will not only compress dry bran to a much greater density than we require, but will compress hay and straw to the density of maple.

It will not do in this age and generation for any man or set of men to proclaim to the world that what they may not be able to accomplish is impossible. Mr. Blinn's machine may equal his ambition—be satisfactory to him—but will not help us to export our bran as at present represented to work."

AN IMPROVED BELL TELEPHONE.—M. D'Arsonval, a French electrician, has devised a new form of Bell receiver, which, for its size and weight, is claimed to be the most powerful yet constructed. According to the description at hand, the chief modification consists in inclosing the hobbin entirely between the poles of the magnet, this being done by making one pole of the magnet the core of the hobbin, and the other pole an inclosing ring of iron. The inductive plate vibrates over the poles and upper surface of the coil as before. The complete instrument is said to weigh only a little over five ounces, and to be as powerful as the heavy flower-Bell receiver.

Manufacture of Machinists' Tools.

The state of business among the manufacturers of machinists' tools indicates the industrial prosperity of the country with almost unerring exactness, at any given time. Are the times good? Is business booming? Is money plentiful? Then we may know that railway securities are easily negotiated, and that money is available for railroad extensions and renewals. The mechanical industries in all their departments, equally feel the impetus of a new life. Shops for construction and repairs are wanted, either on a larger scale or in new locations, and at once orders pour in upon those who furnish lathes, planing machines, steam hammers, punching and shearing machines, drills, etc.

Of late, tool manufacturers complain that orders for new work come in very slowly, so that the ordinary force of men can be retained in employment only as they may have yet in hand old orders partially executed. This sluggish condition of things is felt by the largest and most popular and prosperous concerns, as well as the rest. In a notable instance the decline is something like fifty per cent, compared with "flush times" which have gone. The falling off is not confined to any one or more of the leading specialties, such as locomotive building, but all branches of mechanical enterprise seem to be affected. It is observed, however, within a few days, since the decline in the standard grades of iron, and since the return of ease in money, that enquiries are more frequent, encouraging hopes of better times ahead. The present, if a period of uncertainty, is also a period of expectation, from which, it is hoped, all grounds of doubt will soon be eliminated. The question of cheaper iron may be the pivotal point upon which the issue turns. At least, it is well known that large contracts for steel rails and other materials are held in abeyance, to await the course of events in the immediate future. A more general movement of the various products of agriculture, such as naturally attends the resumption of internal navigation, and especially a more confident assurance of abundant crops from the approaching harvest, or from seed now going into the ground, may suffice to inaugurate a brighter day.

LARGE STEEL CASTINGS.—Owing to the rapid and very extensive growth of the manufacture of Siemens steel in Scotland, there has of late been somewhat extraordinary demand for large anvil blocks, and during the past few weeks two of immense size have been cast. Referring to these, our contemporary, *Engineering*, says that up till now there has not been many anvil blocks in Scotland weighing more than 140 tons, but recently one was cast at the Dalziel Steel Works which is said to contain 170 tons of metal. There is also in progress at the steel works of the Govan Forge and Steel Co., Glasgow, an anvil block which is estimated eventually to contain about 165 tons of metal. In both cases these anvil blocks are intended for use with twelve-ton steam hammers, of which there are now several in regular work in Scotland. The Govan anvil block will be in two pieces, the larger of which, weighing about 140 tons, was finished a short time since. It was cast in a mold occupying the position which the block will occupy after it has been slightly cooled and canted over upon its proper base. The other portion, which will form the top piece of swage-block, and weigh about twenty-five tons, will be cast in a short time. The mixture used in the anvil blocks under consideration was about one quarter No. 3 Gartscherrie and three quarters scrap cast iron.

TESTING SCALES.—The new testing scales in use at the office of the local Inspectors of Steam Vessels of this city are the most accurate ever invented. It is used to test the strength of the iron to be used in the construction of steam boilers, and has a testing capacity of 76,000 pounds. The metal to be tested is firmly grappled, and the powerful double fulcrum lever is made by one man to exert its ponderous power, dragging the strongest steel asunder like molasses candy till it snaps. A self-acting marker moves over the horizontal scale-beam by a system resembling clockwork, and denotes the gradual amount of power applied, and stopping instantaneously with the breaking of the iron tested, gives the accurate test. All of the tested samples are carefully tagged, showing the test applied and for what boiler intended, and kept in boxes for future reference, as, for instance, when a boiler bursts, its strength of material may be officially ascertained.

CALIFORNIA MECHANISM.—Drawings of the new locomotive "El Gobernador," now being built at the Sacramento shops, and which will be the largest locomotive in the world, will be sent to the Chicago exposition of railroad appliances. Master Mechanic A. J. Stevens, of the Sacramento shops, will also send a model of his improved valve motion for locomotives, which, it is claimed, will effect a saving of thirty-three per cent in steam.

A NEEDED INVENTION.—The Philadelphia *Press* says: "The man who can inform the United States Government, before July 1st, the best way to destroy the printed revenue stamps in the bank check-books without destroying the check blanks, may possibly hear of something to his advantage by communicating with Secretary Folger."

SCIENTIFIC PROGRESS.

Improvements in Secondary Batteries.

In a report upon an improved form of the storage battery lately made by Prof. Henry Morton, he found that one cell containing 16 plates, whose united weight was 48 pounds (and with lead-lined box and liquid included, 80 pounds), when fully charged would yield a current of 32.3 amperes at the beginning and 31.2 amperes at the close of a continuous discharge for nine hours. The current supplied by 50 such cells connected in series, will suffice to run 44 Edison incandescent lamps for nine hours. If fewer lamps are used with the same battery, they would be operated of course for a proportionally longer time. Thus 11 lamps would be supplied by a 50-cell battery for 36 hours continuously; or, as lights are commonly used in private houses on the average for 5 hours each night, such a battery once charged would operate 11 lamps for a week. To express the relation between weight of battery and power, it may be said that for each lamp operated for 9 hours, 11.7 cells of battery would be required, or a weight of about 90 pounds of battery. This would be, for each hour of burning each lamp, 10 pounds of battery.

As compared with the recent experiments on the Faure storage battery, made by M. Tresca at the Conservatoire des Arts et Metiers, in Paris, these results show a decided superiority. Thus, in Tresca's experiments a cell weighing 95 pounds yielded a current representing 793,791 foot-pounds of energy; whereas the results obtained by Morton with the new battery weighing but 80 pounds, represented a yield of 1,826,168 foot-pounds. This, in comparison with the yield of the Faure battery, exhibits more than twice the energy with one-fifth less weight.

As respects the efficiency of this new battery in delivery—that is, the amount of current given as compared with that used to charge them, the results are reported by Prof. Morton to be remarkably good. He reports, in other words, that he is able to obtain from these batteries 90 to 91 per cent of the current used to charge them, which greatly exceeds the results obtained by Tresca with Faure's batteries, who reports a loss in charging and discharging of 40 per cent; and Messrs. Perry and Ayrton, who make the loss 18 per cent.

Lastly, on the important question of retaining the charge during a long time, Morton reports that he charged three cells and locked them in a closet on February 1st, and allowed them to remain until February 16th, when he commenced discharging them at the rate of 32 amperes, continuing this rate of discharge on the next day. He thus obtained 260.7 ampere-hours of current. Comparing this with the 286.5 ampere-hours of current obtained from three other cells which he discharged soon after charging them, the result shows a loss of only seven per cent in standing unused and charged over sixteen days.

These experimental results appear to indicate a decided advance in practical efficiency for these batteries.

SCIENCE AND RELIGION.—A long and very able review of the new book, "Where, What, Where?" appears in a recent number of the *Chicago Times*, in which the writer regards the book as a pioneer in the desirable work of "harmonizing science and religion." We have never felt that there were any antagonisms between *exact* science and *true* religion. Speculative science and speculative religion will always be at loggerheads, and the contest can have but little interest to the thoughtful and observant. When the indefensible dogmas which now embarrass and distort both religion and science are eliminated, it will be seen how impossible it is that *truth* can antagonize itself. The most thoroughly scientific man must by the influence of knowledge be the most religious, and so the religious man must be upheld and supported by science. The trouble is, that men of research, students in science and theology, are biased by theories and speculations, and by unwarrantable dogmas. Science teachers presume to tell us what is possible and what is impossible; religious teachers, what we must believe, and what we must not believe. The material and spiritual insight is clearer to-day than it was yesterday, and the next century will witness advances, the magnitude and beneficence of which we can scarcely now conceive of.—*Popular Science News*.

THE ELECTRIC LIGHT IN PARIS.—It is not uncommon to meet in our streets peddlers of kerosene going from house to house vending their illuminating fluid from a can. In Paris the electric stored light is carried about the streets like kerosene here, and it is said to have become a favorite way of illuminating houses on social and official occasions. The accumulators are carried in a vehicle, which is stationed in front of the house, and electric wires are conducted into the building through the windows. Incandescent lamps are placed in the ordinary candelabras, and the fitting of the most complex lighting is an affair of but a very short time.

SIRE'S PENDULUM.—M. Sire has presented to the French Academy a modification of Foucault's pendulum, which accurately exhibits the laws of displacement in whatever latitude the experiment may be tried.—*Comptes Rendus*.

An Interesting Discovery.

According to a French paper, the *Echo du Nord*, a number of coal mines in the north of France are about to be visited by a band of explorers of great distinction. Messages were recently sent from the place in question to the Academy of Sciences, in Paris, and to the authorities at the British Museum, inviting delegates from each of the bodies to pay a visit to the subterranean passages, where an uncommon discovery is said to have been made. The paper in question relates how, in excavating a new passage, the miners came across some extraordinary fossils, proving the presence there, at some remote period, of human beings, as well as of animals and fishes. The passage in question led, as it appears, into two caverns, the mouths of which have long been closed up, and in the first of these were discovered five perfect fossils—one of a man, two of women and two of children, besides several weapons and utensils of petrified wood and stone. The second cavern, discovered some time later, contained no less than eleven fossil bodies, described as being of large dimensions, a quantity of miscellaneous objects, and some precious stones. In addition to this, it is ascertained that the walls of the cave were covered with rude sketches representing the combats of men with gigantic animals, from which it would appear that the human race, while battling for existence with the aid of stone axes against the monsters of the field and forest, were still acquainted with the graphic arts, and anxious to perpetuate their deeds of early heroism. The bones and bodies themselves have now been removed to the neighboring towns of Lens and Lille, in the latter of which places they were recently exhibited.

A NEW PROJECTILE.—Mr. J. D. Cable, of Pittsburg, Pa., has applied for letters patent for a shell which, as a destructive weapon, is claimed to be unequalled. It is a nitro-glycerine bomb, and is described as follows: A heavy conical shell is first cast, and so arranged that one end is much heavier than the other. One end is closed with a tightly-fitting cap screwed on after charging. The interior of the shell is divided into three compartments, each separated by a heavy plate-glass cap. The division furthest from the open end is filled with sulphuric acid, the next with glycerine and the outer one with nitric acid, these three elements being the component parts of nitro-glycerine. A small opening through the center of the cap fitting the open end of the projectile admits a steel rod, to each end of which is firmly attached a small circular piece of metal, the inner end resting against the first glass cap. The outer cap is then screwed on and the projectile is ready for service. According to the principle of gravitation the heavy end naturally strikes the ground first, the steel rod is driven through the plate-glass partitions, the chemicals are mingled and a nitro-glycerine discharge takes place. The inventor claims that if such a projectile should strike a vessel it would have a disastrous effect, and as a means of reducing intrenchments it would be serviceable beyond measure.

MAGNETIZATION OF IRON AND STEEL BY RUPTURE.—At a recent meeting of the Society of Physical and Natural Sciences, at Karlsruhe, Germany, Mr. Bissinger dwelt at some length upon the phenomenon of magnetization of iron and steel when broken in the testing machine. The phenomenon is ascribed not to the elongation of the bar, but to the actual fracture, and both parts are converted into two magnets of sensibly equal power. The shock and vibration of the metal on breaking, is in all probability the cause of magnetization. In testing bars for tensile strength, the south pole is formed at the upper end of the bar, and it has been found that the different iron objects near the machine at the moment of rupture are also magnetized, but to a less degree.

AN OLD STORAGE BATTERY PATENT.—Electricians are interested at present in the discovery in the Patent Office of a patent issued February 6, 1861, to C. Kilchof, a New Yorker, for an electric battery, which presents all the features of the storage batteries in use at the present day—lead plates immersed in acidulated water, which becomes coated with the oxide of lead. The principle appears to be the same as that of the Plante (French) storage battery, and the storage batteries now in market must hereafter rely upon peculiarities of construction instead of comprehensive claims.

THE GEOGRAPHICAL SOCIETY.—At a meeting of the geographical Society of this city last week, J. C. Flood was made an honorary member. A lengthy paper was read by G. P. Lansing, on "The Influence of Early Arabian Inter-course with China." The essayists had grouped together a large number of facts bearing on the interesting theory that Europe owed most of its early progress in arts and sciences to the centuries of commercial intercourse between the Arabs and Chinese; the former thus introducing the latter's civilization into Europe.

STILL ANOTHER NEW THERMOMETER.—Prof. Tait announces that by means of pure iridium and ruthenium he has been enabled to construct a standard thermo-electric thermometer, capable of reproduction anywhere, and which would afford a perfectly definite standard for the comparison and measurement of high temperatures, for which at present no proper instrument exists.

Mining Share Market.

There has been quite a little flurry in mining stocks this week as our table shows. The general impression seems to be that developments will be made shortly on some of the Comstock mines. Senator Fair has gone away to Europe and left the Comstock to its fate, even giving it something of a "set back" in an interview with a reporter, notwithstanding which, prices have been firm. The Virginia Enterprise is conservative on the subject, and in an issue of recent date says: Prices are still low for leading stocks, and the developments made would perhaps justify still higher prices at some points, but purchasers should bear in mind the fact that as yet no new bonanza has been struck. We are always desirous of saying the best that can possibly be said for every mine on the Comstock, but just at present we can see no foundation for a boom. The San Francisco people appear to think differently, and are now managing things to suit themselves.

At the north end there is as yet no sign of ore in the Sierra Nevada and Union Consolidated winze, but doubtless when the 3000 level is reached and a drift run west a deposit of value will be found. The fine showing of ore on the 2900 is proof of this. Should it be thought worth while, this ore might now be followed down by means of winzes. It is of rather low grade, and such a plan of working would be poor economy.

At the south end of the lode quite a bonanza of low grade ore has been found in the Yellow Jacket. In the Belcher and Crown Point a good deal of ore is in sight in all the openings.

It is said 100 Mormon immigrants from Switzerland, poor, ignorant, and in many cases infamable creatures, to get rid of whom the communes are willing to pay 160 francs per head, are coming by the steamship Nevada, of the Guion line, which left Liverpool on May 16th.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

MAMMOTH.—*Ledger*, May 26: Senator J. P. Jones and others have secured an interest in this prominent mine. A working capital of \$100,000 is to be put in the treasury for a systematic development of the claim. A tunnel is to be run from near the Mokelumne river. This will strike the ledge on the Mammoth ground at a distance of about 800 feet from its mouth. It will then have to run over 1,000 feet more to reach underneath the present shaft. It will tap the ledge at a depth of nearly 1,000 feet. The tunnel is to be of a most substantial character, supplied with a double track. Operations were started on this undertaking last week, and it will be pushed ahead with all possible speed. As soon as the ledge is struck, the intention is to put up a 40-stamp mill. The tunnel will take at least six months to complete, making an average of 10 feet per day. Air compressor drills will be used, operated by water power by means of one of Knight's wheels. The same water that runs the mill, can also be used to run the drills. It is estimated that the construction of the tunnel will cost from \$25,000 to \$30,000.

BUNKER HILL.—We are pleased to be able to report a prosperous state of affairs at this mine. The ledge of good milling ore encountered in the footwall at the 500-foot level continues to yield well. About 30 feet have been stoped out at the north end, and the face looks as well as ever. One clean-up has been made, which realized something over working expenses, but how much we are not prepared to state. It is satisfactory to know, however, that all the hands were paid off promptly at the end of the month, and also the first installment on the old indebtedness was paid at the time agreed upon. The present run is expected to turn out even better than the previous one. Free gold is occasionally to be seen in the ore. From 25 to 30 men are employed, and 10 stamps of the mill are running. The ore is being extracted from the 500 and 270-foot levels. The property is being judiciously managed under the superintendency of N. W. Crocker, with J. W. Truscott, a first-class practical miner, in charge of the underground works.

MISCELLANEOUS.—The Loyal Lead is being vigorously worked. A 10-stamp mill is pounding away steadily on ore taken from the long tunnel running south. A substantial track, some 500 or 600 feet long, enables the ore to be run easily to the mill. One clean-up has been made, and we understand the amount came up to the expectations of the owners. At the South Spring Hill claim sinking is being prosecuted. The shaft is over 500 feet deep, and the indications are of such a character as to induce continued sinking. Eight of W. Moon's teams are busy hauling rock from Morgan's claim to the Kelly mill. They are putting it at the mill at the rate of 45 tons per day. The mill is running full swing, and crushing it about as fast as it is being hauled.

VOLCANO.—*Sentinel*, May 23: Volcano is no duller than other towns where water in proper quantities and in proper times makes prosperity. The late rains very much aided the small mines; the large hydraulic mines were not helped, however. The output from this district will be considerable. The Downs mine has good rock for a 40-stamp mill; its capacity is only 20 stamps. The ore is good working ore, averaging \$20 per ton. Mason's prospect on Kate Gray gulch is most gratifying. He has a three-foot ledge, with good defined walls. The pay chute or chimney is over 200 feet long. The rock prospected will reach or exceed \$40 per ton. The Pioneer district is looming up. The Moloc has 150 tons of ore on the dump. No one estimates that it will average less than \$40 per ton, and six men can keep the mill (10 stamps) running continually on the same rock. The Stoken mine looks well. Twenty-five tons are on the dump, which experts average at \$60 per ton, with a good ledge. The Tunnel Co. has cleaned up. The amount taken out I do not know. Enough has leaked out for us to know that the ground is far richer than last year, and the return is gratifying to the owners. Hadley & Vail have water for three weeks' more run, and will not clean up till the end of the season. They are doing well. Geo. Evans, at Rancheria, is in the same fix.

Calaveras.

MINE SOLD.—*Chronicle*, May 22: The quartz mine known as the "Star of the West," located at Skull Flat, about three miles from West Point, and owned by Mr. Carey of that place, was recently purchased by a party from Sacramento. The mine has been idle for some time, but operations are now to be commenced upon it at once. The amount for which the property was sold we did not learn.

NOTES.—*Mountain Echo*, May 22: We learn that work will soon be commenced in the Jack Rabbit, near Monarchville. We understand that preparations are making for the erection of a mill on the Morgan mine at Carson's. Twenty more stamps are to be added to the Gold Cliff mines as soon as the material can be obtained. Mining prospects are daily growing better in this section. There are at present seven or eight arrastras running steadily and paying well. Also, two mills—one ten and the other twenty stamps—and several more in course of construction.

El Dorado.

BENFOLD'S GRAVEL MINE.—*Mountain Democrat*, May 26: On Tuesday of last week, Fred Benfold started up again at his gravel mine near Smith's Flat, which had been shut down since the cold weather had frozen up the water with which his machinery is run, and compelled him to stop. Of course, in the meantime the lower works had filled with water, and it was a matter of considerable trouble and expense to restore affairs to their former condition. He has about twenty-five men at work, which force will probably be increased to forty or fifty within a short time. This mine is the mainstay of Smith's Flat, which, if a new bench is struck soon in the Kum Fa, as is confidently predicted, will be one of the liveliest little camps in our country.

RICHER THAN EVER.—At the Mount Pleasant mine, Grizzly Flat, they have been sinking the main shaft from the 400-foot level, with the intention of running a new level at a depth of 500 feet from the surface. Before starting the new level they must

sink to a depth of 515 feet, the additional 15 being for a sump. Last Sunday morning, about three o'clock, having reached a depth of about 507 feet, a body of high grade ore was found making into the shaft, quarter

the pay chute is still going downward and eastward according to its usual direction. The distance between the 13th and 14th levels is 200 ft., which will save a large amount of new backs. The sinking of the incline below the 14th level will be resumed as soon as the water power connections are made to the pumping and hoisting work, which is now only the matter of a short time.

Placer.

THE ORE ROASTING SYSTEM.—*Placer Herald*, May 18: The roasting furnace in operation at the old Blossom mine seems to be just what the miners of this county have been waiting for, viz: Something that would save a larger percentage of the gold at a moderate cost. Most of the ore from the ledges in this part of the county will assay from \$50 to several hundred dollars per ton, and yet by the mill process is considered good rock that returns from \$10 to \$5 per ton. By the furnace process above referred to the gold and silver can be saved close up to the assay value, and we understand the expense of the process is comparatively light. There is encouragement would seem, for others to adopt this process, and with a dozen or more of these roasters in operation this neighborhood this would be a lively camp. Even by the old process the returns being received from the different mines in this locality at present are together encouraging.

A NEW MINING LOCATION.—*Placer Times*, May 18: A few weeks ago parties from Sacramento, and a new location partly on the old abandoned Alta Belle gravel mine, at Alta. The new claim is called the Alta Placer Mine, and contains 140 acres, section 36, 15 north, 10 east. S. Spencer and R. Reed, were up from Sacramento, Saturday, and completed arrangements to commence work in a short time. A stock company will be incorporated and shares offered for sale. The claim will be drifted through an incline shaft started in the Shady Glen Placer Mine ground, adjoining on the south. Work on the old Alta Belle mine, about 11 years ago, satisfactorily proved that a rich lead runs through the claim. The last day's work turned out \$16 a day to the man, but on account of a continuous litigation with reference to title, work was suspended. Miners who are acquainted with the ground certify that it is the richest of any in this section. The new company can confidently expect to strike a big thing when the incline gravel channel is opened out thoroughly.

THE IRON FURNACE IN OPERATION.—*Placer Herald*, May 26: The iron blast furnace andundry buildings, at Hotelling, destroyed by fire some time ago, have all been replaced on an improved plan, and after some delay, caused by defects in the elevators, the blast was put on last Saturday, when everything, we learn, worked smooth and quite satisfactory to those in charge. They have already added a pile of new iron in the yard, and every prospect before them for a successful summer's run. According to one authority they have on hand 14,000 cords of wood, 300,000 bushels of coal, and 8,000 tons of iron ore. They are at present working two deposits of ore, both of which yield a high grade, and are extensive. More or less improvements have been made in and around the town, including a new office for the superintendent and other new buildings. Together the place promises to be more prosperous in the future than even before.

Plumas.

ARADIAN MILL.—*Greenville Bulletin*, May 23: Ore from the Sunset ledge continues to be worked in the mill, giving results thus far as good as was reached during the previous month.

PLUMAS CON.—A vein of ore about four ft wide has been struck in a prospect tunnel, the ore is of fair quality, the ledge appears to be well defined, and stands nearly vertical. It is thought that this vein is only a stringer, and will soon run into a much larger ore body. This and other circumstances are likely to put the Plumas Con. in a prosperous condition before long.

INDIAN VALLEY MINE.—About 6 A. M. to-day the pinions of the hoisting engine were completely tripped of teeth, the thing was done in a moment, and the engineer instantly applied the brake which held good and no further damage was done. Mr. Harland, the superintendent, was on hand in a few minutes and had men at work clearing away the broken machinery; he will push the work with his usual energy so that the delay occasioned will not exceed a week.

WILES LEDGE.—Years ago two brothers named Wiles worked a placer claim on the west side of the reservoir, at Round valley; they took out a good deal of money and then sold the claim to parties who never tried to do much with it. For some months past John Ellis has been prospecting on the same ground for quartz and before the late storm set in had found a ledge; when water began to run a stream was turned along on the top of the ledge and it washed off for a distance of 60 ft or more. So far it uncovered the vein averages over five ft wide and prospects from 20 to 30 dollars per ton. The parties interested propose to lease the Kettle mill and proceed at once to work the mine; the distance from the mine to the mill is only a few hundred yards, the ore can be got and worked very cheaply.

San Bernardino.

BULLION.—*Calico Print*, May 19: Last Wednesday 345 pounds of bullion were shipped from the Silver Odessa mill, at Hawley's, valued at \$5,300, being the returns from Alhambra ore. Yesterday, 155 pounds of bullion, valued at \$2,400, were shipped from the Oriental mill.

PROVIDENCE ITEMS.—There has been shipped for the first two weeks of this month by the Bonanza King Con. mill, \$33,258, besides considerable unreported amalgam. The shipments for the present month's returns will not be less than \$70,000. The Belle McGilroy and Mozart group of mines have been bonded during the past week to San Francisco parties. The bonds compel them to work during the coming months. A large force of men will be sent from San Francisco to start up the works. C. N. Hasson and W. B. Caldwell left this morning for the west side of the mountains on a prospecting tour. The ore dumps of the Bonanza King have been largely increased during the past two weeks.

AT THE LAVA BEDS.—Messrs. S. H. Baker and J. M. Parker, and another gentleman, are now at the Lava Beds working on some claims that they had located. They have run in a tunnel on one claim a distance of thirty feet, and the showing is good. They are now sinking a well in the alkali flat near the Clark mine, and are down about twelve feet.

They believe that they will succeed in getting plenty of water, which will be of great value in developing the mines.

THE IREX MINE.—*Calico Print*, May 26: The Irex mill is completed. She started on Monday, May 21st, on the poorest ore, and as soon as the crevices are filled in they will commence on the best ore. The mill is the best and most complete little raw working mill that can be seen anywhere, and quite different from other raw working mills. She can be made, by the addition of a Howell Chloridizing Furnace, a first class roasting mill. She has for that purpose wood sides to her pans and sculer, and the necessary Howell millers, dies and movable miller arms with Stevenson's millboards set in cement. All this is different from the ordinary iron side pans, so common in raw mills, and so valueless if the mill at any time is changed so as to work roasted ore. The machinery is entirely new and first class, and the manner in which she is built does credit to the architect, O. Crandall, Esq., of San Francisco, who left nothing undone to make her the first class, complete, solid little mill that she is. The man who does such work without any specifications or written contract, other than a verbal agreement, as was done by Mr. Crandall, is worthy of appreciation.

Shasta.

FURNACEVILLE.—*Cor. Shasta Courier*, May 22: The Afterthought mill shut down a few days ago for repairs; but the actual cause though, was no wood, as on account of the recent long continued rains the roads were in such a condition that hauling could not be done. The prospects are very good, but on account of the limited amounts of necessary works, such as agitators, pans, leeches, etc., the stamps can only be run a small portion of the time; the result, however, of the ores put through is very favorable. Mr. Stewart has just sent down by Mr. Rediker another truck, and at the mill there are 30 sacks of 150 lbs. each of cement copper ready for shipment, that yields about 85 per cent; former shipments have always made satisfactory returns. About 25 men are now employed in and about the mill. Messrs Morley & Salsbury have a claim in the district, near the Afterthought mill, that prospects well in gold; they are now running a tunnel on the vein, and talk of putting up an anastra.

Sierra.

THE PLUMBAGO MINE.—*Sierra Tribune*, May 26: A gentleman from San Francisco examined the above property last week, with a view of making a report on the same to an English company. The Plumbago quartz mine is located at Minnesota. The mine has been opened sufficiently to prove that it could be made a big paying property if properly handled.

SAVAGE MINE.—J. Minor Taylor is expected to arrive here from Virginia city soon to start up work at the Savage mine. The recent developments made by the Bald Mountain Extension Company is liable to create a boom all along the ridge this summer. It is the opinion of all those who have paid any attention to the workings of the Savage mine that a channel will be uncovered in that claim at an early date.

CHINESE MINERS.—Seven or eight Chinamen have built flumes and a dam, erected a derrick, and made other preparations for mining the ground in the creek by the Masonic hall, and upon which Mr. F. D. Soward's building stood. It is quite interesting to watch the heathens hunt for gold.

NEVADA.

Washoe District.

SIERRA NEVADA.—*Enterprise*, May 26: On the 2900 level the joint Union Consolidated winze is now down nearly 70 feet. It is in a favorable formation, and is being sunk at the rate of nearly 20 feet per week. It will be eventually put down to the 3700 level, where it will connect with the drift now going north from the joint Ophir and Mexican winze. The end of the ore has been reached in north drift No. 2 on the 2900 level.

HULE AND NOCKROSS.—The station for the winze is almost completed. In cutting out this station a new streak of good ore some ten inches wide was encountered. These streaks appear to widen in going down, and are probably the top of a deposit that will open out when followed down by the winze. There is no trouble with water. The ore is of a strong appearance.

BEST AND BELCHER.—The northwest drift on the 2500 level is being advanced in ground that is hard and dry. It has been long since there has been any crosscutting in this mine. They will soon be in a position to make extensive explorations.

UNION CONSOLIDATED.—In south drift No. 2, on the 2900 level, the end of the ore deposit has been reached.

YELLOW JACKRABBIT.—The mine is yielding well at nearly all points. Quite a bonanza of low grade ore has been found in new ground on what the miners term the "Frog Pond Level." This is really quite a valuable discovery. The mine is really looking very fine throughout.

OPHIR.—A considerable quantity of ore is still being extracted from the croppings, and this work will be much facilitated by the opening out of the old tunnel.

CHOLLAR.—In crosscut No. 3, on the 2600 level, good progress has been made during the week in quartz of a good appearance, though not carrying much metal.

Bald Mountain District.

FREE GOLD.—*Eureka Sentinel*, May 26: Luther Clark returned from Bald Mountain yesterday, bringing with him some specimens of white quartz, showing specks of free gold. This character of rock is abundant in Bald Mountain district, in wide ledges, which crop out boldly on the surface, but have not been prospected to any considerable depth. A number of years ago Pete Lovell tried an anastra on the ground, and washed the gravel in one of the canyons, but it did not pay very well, owing to the scarcity of water. The principal feature of mining in Bald Mountain district is the excellent prospect it offers of showing up valuable copper mines. Fine surface bodies of copper have been uncovered, but the deposits, as in the case of the gold ledges, have not been worked deep enough, except in the case of George Lamoureux's claims, and one or two others, to prove whether they will be of permanent value or not. Judge Adams is on the ground, comfortably housed in his new cabin, and is about to begin his summer's work prospecting.

Columbus District.

THE LUCKY HILL STRIKE.—*True Figure*, May 26: Within the present month another bit of pleasant news has been given to this community, and one that again brings to the front the Columbus mining district. The property of the Lucky Hill mining company adjoins that of the Columbus Consolidated on the west, and it was thought the body of ore found in the latter extended into the ground of the former. Accordingly a shaft was started about 200 feet from the line, and at a depth of but a few feet a ledge 20 feet in width was encountered, which contains some fair, good and high grade ore. An average of the whole gives fine assays, and as the work continues, the outlook is highly encouraging.

NORTHERN BELLE.—Sinking has been commenced on a streak of ore found on the eleventh level, which, it is thought, will connect with the body of ore encountered above the first shaft level. The prospecting operations in all parts of the mine are being pushed ahead as rapidly as possible, and all work in and around the mine is progressing satisfactorily. The daily output of ore has been about fifty-four tons. Both mills are running steadily and doing good work. The bullion shipments amounted to \$14,741.83 for the week ending May 24th, and a total of \$42,155.33 has been shipped on May account to the same date.

MOUNT DIABLO.—The slope above the west drift from the Fallon winze is looking well; the west end shows 2 feet of \$80 ore, while in the center there are 3½ feet of \$75 ore. A little ore is being stored from a point on the first level, near the shaft, and also from the Mount Diablo adit. Two bullion shipments were made during the week—one on the 17th inst. of \$6,140.04, and one of \$7,503.39 on the 25th.

Eureka District.

ANOTHER FURNACE.—*Eureka Sentinel*, May 23: Another furnace will be started up to-day at the Eureka Con. reduction works. The bins at the works are filled at present with Eureka Con. and tribute ores. The idea in starting up another furnace is to get the mass of this ore out of the way, in anticipation of increased shipments from the Eureka Tunnel in a few days upon the completion of the new shaft, through which it is calculated ore will begin to be hoisted by steam next Sunday. It is understood, also, that arrangements will be completed within a very short time by which ore will be allowed to be shipped for reduction from the Albion. The tributers in this mine are reported to be doing very well in their pitches, from which, and from other parts of the mine generally, it is believed enough can be shipped to help out materially in keeping one furnace at work. In connection with this it may not be out of order to say that a number of mines on Prospect mountain are looking well, and give promise altogether of a good ore product this summer. If the outlook is not deceptive, there will probably be enough custom ores shipped to the Eureka Con. works to keep the additional furnace running for some time. If they strike ore in the Locan shaft, as is expected, we may speculate upon the starting up of the remaining furnace before the opening of another winter. This is a consummation devoutly to be wished, and we'll hope for it if we can't do anything more.

A NEW DEPARTURE.—*Eureka Sentinel*: The steam hoisting engine at the Eureka Tunnel will start up to-day. This will mark an important epoch in the history of the mine. From to-day on the facilities for working will be greatly enlarged, and ore shipments very much increased. With the powerful aid of steam developments will be rapidly pushed forward, and the mine thoroughly explored at greater and greater depth. We may say that to-day the first step was taken towards solving the problem whether Prospect mountain is, what it is supposed by miners in this camp to be, a rich and extensive deposit of paying ores.

Jackrabbit District.

KING FISHER.—*Pioche Record*, May 18: On Tuesday we took a flying trip out to Jackrabbit district for the purpose of looking at this much talked of claim. We found there had been very little work as yet done on the claim, nothing but the lime cap having been removed. At the place where it is intended to sink the shaft, there is a gray carbonate ore, the ledge being claimed to be 18 ft in width. The assays from this ore range from \$20 to \$100. All indications here tend to confirm the belief that there is a large deposit of ore at this point. A few feet up the hill, in a hole about three feet in depth, between the surface dirt and cap rock, there is a seam of soft, rich yellow ore, we should judge from four to seven inches in width, which assays from \$150 to \$600, and of course picked pieces would show up into the thousands. This character of ore has been taken out at several places on the surface, always found between dirt and cap. About three tons of this rich ore have been extracted. This claim has a remarkably excellent top showing, and if the gray carbonate should develop into the body of ore that its owners believe it will, they then will have a good and valuable mine. The King Fisher is an old Burrows location, then known as the Blue Bird. During the week word was sent in that a shot had been put in the gray carbonate ore and that about 20 tons of good ore was broken. It appears to be an immense blow out.

Safford District.

STRUCK ORE.—*Eureka Sentinel*, May 26: A letter received from Palisade last evening states that a fine vein of ore has been found in the Illinois claim at Safford. This mine is owned by T. R. Jewell and O. W. P. Bailly, and joins the celebrated Onondaga on the west. Work has been continuously done on this claim, but until yesterday no ore of any importance had been discovered, though its close proximity to the Onondaga has always led the owners to believe that mineral in paying quantities would be found.

ARIZONA.

OLD DOMINION COPPER.—*Globe Chronicle*, May 19: Furnace No. 1 of the Old Dominion Co. was started last on the 7th of April and has been running continuously ever since, producing for the 41 days ending at 7 o'clock yesterday morning 298,155.9-2000 tons of bullion. Furnace No. 2 was started on April 18th and had also been in constant operation, the joint product of the two furnaces being 474,710-2000 tons. The single and joint runs of the furnaces are the best on record. Furnace No. 3 was started up. All three of the furnaces are now running regularly.

COLORADO.

LEASING MINES.—*Register-Call*, May 23: Thomas McCall, William Agnew, J. J. Reilly, Richard Jenkins, Willis Marks and O. P. Russell, have taken a lease of the James Henry lode on Gunnell hill. Two drifts are being driven at the respective depths of 40 and 105 ft. Yesterday they were engaged in clearing the main shaft of accumulated water.

E. W. Henderson, E. S. Mills, Robert E. Morris, Nate A. Sears and David Winton have taken a lease of the Whiting and Butler mines on Gunnell hill. They are sinking the main shaft on the former vein, which is now down to a depth of 225 ft. and drifting both east and west. East of the Whiting, L. R. Wolcott and Wm. Bowdin have sub-leased what is now known as the Spur lode, a feeder to the Whiting. They are sinking a shaft to make a connection with a drift on the Whiting, where it is claimed there is a body of mill dirt.

The usual number of miners are employed on the Gunnell, the principal portion of the work being done by tributers.

The Prize mine, worked by J. W. Bostwick, Den Sullivan and others, are taking out a good quality of mill and smelter ore.

Wm. Richards continues development work on the Jones. Both the milling and smelting ore keeps up to its former standard.

A pool of miners has been formed in Nevada to work the property of the Gilpin County M. Co., on the Burroughs lode. There is a good plant of machinery over the mine. Work has been commenced, and as the pool is composed of practical miners, good results from their developments of that portion of the Burroughs can be anticipated.

IDAHO.

THE ONTARIO.—*Ketchum Keystone*, May 22: This mine exhibits a beautiful body of galena in the breast of the latest work, ore that is nearly three feet thick and perfectly solid. Ore has been taken from it in large quantities for several days and still the vein holds out with remarkable richness. Two men are at work on the Black Horse claim.

FORTY-TON SMELTER-PLANT.—*Wood River Times*, May 26: It is stated that Supt. Chase, of the Davitt mine, on Deer creek, is taking definite action toward the construction of a 40-ton smelter-plant adjoining the Bailey sampling works, below town, which will have all the latest improvements, including Cornish rollers, and all needed appliances for successfully treating Wood river ores, the works to be finished early this season. The project seems to be so far well inaugurated, and if the works are completed there will be another home market made here for ores, and the number of men which will be steadily employed by the work will add to the prosperity of the town. Mr. Chase and the Davitt Co. are said to mean to have a smelter here, even if they are compelled to build it themselves.

MONTANA.

VARIOUS MINES.—*Inter-Mountain*, May 22: The Mount Moriah continues to produce 15 tons of ore daily. Good ore has been struck in the south 320 ft crosscut of the La Plata. Preparations are being made to sink the main shaft of the Colusa to the depth of 400 ft. It is now 260 ft deep. The Montana smelter is now running at full blast. It is reported that Wm. McCaskle will have charge of the Anaconda smelter when completed. The Moulton now ranks as one of the most reliable producers among the silver mines in Montana. Work has been temporarily suspended on the Shakespeare on account of the departure of Mr. Claggett, one of the owners. The immense strike in the Poser holds out in fine shape and is proving one of the most important ever made in the district. It is the intention of the Anaconda Co. in the near future to put upon the St. Lawrence a similar hoist to that on the Anaconda. The surface cut on the Magna Charta is producing daily 20 tons of ore assaying from \$50 to \$90. The Parrot mine under first-class business management, is moving on the even tenor of its way and has no trouble in supplying the smelter with all the ore it can treat. The daily output now is about 60 tons. The Gagnon is opening up fine on 500 level. In the 400 level the vein was somewhat segregated, but in the new level it is all together, and the face of the east drift presents a compact ore body seven feet wide, assaying from \$75 to \$100 per ton according to sample assays. Some of the ore is of very high grade.

UTAH.

PARK CITY MINES.—*Salt Lake Tribune*, May 25: R. Mackintosh who went to Park City the other day made a minute examination of several mines there, and what he says of them is of much importance, he being so familiar with mining matters. The first mine visited was the Crescent, and he passed through all its workings. He says that Mr. Daly, the superintendent, has opened up the property in excellent style, exposing large bodies of ore. The ore at the upper workings of the Crescent property is low grade, and as depth on the vein is attained, it grows richer, bringing the average well up. Mr. Mackintosh classes the mine as being the largest, cleanest and best body of lead ore he ever saw, and says the quantity is so enormous that it is foolish to attempt an estimate of it; that it exceeds the most sanguine expectations of the stockholders. He describes the mine as having all the workings connected, and says that as much ore as there is exposed 100 tons per day may be taken out for the next 12 months, and there will be more in sight than at this time. The Apex he describes as looking well. Work is going on at the top of the ore chute and is liable to open up a large ore body in the belt of the ore zone. On the Silver Key they have drifted 100 ft on the ore chute, where they have two feet of solid ore, which runs from 70 to 120 ounces silver, and the property looks very promising. He visited the Sampson and found the two compartment shaft down 20 ft, and work being pushed. They intend to cut the vein 200 ft below the present workings on the incline. The property he classes as fine and reports 20 men employed. Snow on the Apex ground lies from six to ten feet, and on the Crescent it is nearly gone. The Crescent Co. have a new road up Thayne's Canyon, which they have commenced using, and this enables them to send down 40 tons per day. This will be increased to about double this amount soon. The sampler is handling about 40 tons of ore per day, and expects to handle 100 soon. The Park is looking up, and the outlook is bright.

How a Scale Insect Grows.

Few who are able to recognize scale insects on sight have ever informed themselves accurately upon the progress of growth of the insect from the egg to maturity. The study is one requiring close attention and can be traced only by one who has given much time to the observation of entomological phenomena, but the general reader can by reading obtain an idea of the method and time in development which will be of interest and value.

We propose to expound this matter by the publication of Prof. J. Henry Comstock's account of the life-history of the red scale insect of Florida (*Aspidiotus ficus*), which resembles the red scale which afflicts our orange growers. The appearance of the insect at its different stages is given in the engraving. Of course there are special manifestations in the growth of this insect which are characteristic of it, but in many points it no doubt resembles others of its class.

Prof. Comstock obtained the eggs of this insect from Florida and put them upon orange trees growing in pots in his office in Washington. The day after they were placed upon the trees, April 13, the eggs began to hatch. The newly hatched larva (Fig. 2 c) is broadly oval in outline and yellow in color. The antennae are five jointed; the three basal joints are very short and nearly equal in length; the fourth and fifth joints are each longer than the three basal joints together. The fifth joint is strongly tuberculated at tip so as to appear bifurcated. The eyes are prominent and of the same color as the body. The young larva are quite active, but they settle soon after hatching. Some settled the same day that they hatched.

April 14, it was found that the young lice, although only twenty-four hours old, had formed scales which completely concealed them from sight. These scales resembled in appearance the fruiting organs of certain minute fungi. They were white, circular, convex, with a slightly depressed ring around the central portion (Fig. 2 d); their texture was quite dense, and they were not firmly attached either to the insects or the leaf, a slight touch being sufficient to remove them without disturbing the larva. The larva had not changed in appearance, and were able to move their legs and antennae.

April 15, the lice had not changed perceptibly. The scales had become higher and more rounded.

April 16, the lice had contracted considerably, being now nearly circular, at least as broad as long; in other respects there was no apparent change. The scales were found to vary somewhat; those most advanced having the central portion covered with a loose mass of curled white threads. (Fig. 2 e.)

April 17, there was apparent no further change in the larva; but the mass of threads covering the central part of the scale was found in some specimens to have greatly increased in size, equalling in height three or four times the width of the scale. This mass is cottony in appearance, and in those specimens where it is largest is more or less in the form of a plate twisted into a close spiral. (Fig. 2 f.)

April 19, not much change was apparent in the larva, but the mass of cottony excretion upon some of the scales had increased enormously; so that in some cases it extended in a curve from the scale to a point five times the width of the scale above the leaf and down to the leaf.

April 21, it was observed that the larva had become more or less transparent, and marked with large irregular yellow spots near the lateral margin of the head and thorax, and with a transverse row of similar spots across the base of the abdomen; the tip of the abdomen is very faintly yellow.

April 23, it was observed that the scales appeared faintly reddish in color with the center white; the reddish color, however, was due in part to the body of the larva, which is now orange-red, showing through the scale. It should be noted that in only a part of the specimens did the cottony mass become enlarged as represented in Fig. 2 f. The greater part of the scales remained until this date of the form shown in Fig. 2 e, and the cottony spirals have now disappeared, probably having been blown away.

April 24, some of the larva had become deep orange in color.

April 26, most of the scales had become deep orange in color with the central part white; some had at the center a small nipple-like protuberance; others still preserved a short tuft of a cottony excretion. This tuft is either removed by wind or otherwise, or it becomes compact, melted, as it were, to form the nipple-like projection referred to above.

April 28, the insects appeared as they did two days ago; the scales had become very tough, and it was with difficulty that they could be removed from the insect.

April 30, the insects still remained apparently unchanged. Some of the scales were only about one half as large as others, and still remained perfectly white; they proved to be male scales. All the scales at this date had an elevated ring on the disk, with a central nipple.

May 3, many of the larva began to show that they were about to molt, the form of the next stage being visible through the skin of the insect.

May 5, nearly all of the larva had molted; they were now orange-yellow, with the end of the body colorless. The molted skin adheres to the inside of the little scale, and therefore cannot be seen from the outside. The scales are now pink, or rose colored, with a center white.

May 14th, the insects had become a somewhat paler yellow, with the anal segment slightly darker. Most of the scales were now dark purple. On removing an insect a very delicate round white plate was observed adhering to the leaf where the mouth parts were inserted.

May 18th, the male scales were fully grown. At this stage they were dark reddish brown in color, with the center white, and the posterior side, which is elongated, gray. At this date some of the males had transformed to pupae; others were still in the larva state; these larva were covered with roundish, more or less confluent yellow spots, leaving only the margin colorless; the end of the body was pale orange. The newly-transformed pupae resembled in markings the larva just described. None of the females had yet molted the second time; their color was deep orange.

May 21st, nearly all of the males had changed to pupae. It was observed that the last larval skin is pushed backwards from under the scale, to the edge of which it frequently adheres.

May 24th, none of the male pupae had transformed to the adult state.

May 29th, it was found that during the five days previous more than one-half of the males had issued, and the remainder, though still under the scales, were in the adult state. It was now forty-seven days from the time the larva hatched.

June 2nd, no males could be found; the females were about one-half grown, and were whitish with irregular yellow spots.

June 9th, eggs were observed within the body of a female.

June 17th, it was found that one of the females had deposited nine eggs, of which six had

THE RED SCALE OF FLORIDA. AND ITS GROWTH.

hatched. This is sixty-six days from the hatching of the egg, and probably about twenty days after impregnation of the female.

Two California Mines.

At the recent half yearly meeting of shareholders of the Plumas Eureka, in London, accounts showed a balance on the half year ending Dec. 31st, 1882, of \$141,600. A dividend of \$70,313 was recommended. The quantity of ore produced during the half year was 20,075 tons from the Plumas Eureka mine, 755 tons from the Seventy-Six mine, and 8,630 tons from the Rough and Ready and Elizabeth mines, giving a total output of 29,460 tons. The mills reduced 29,490 tons. The average cost of mining, including prospecting, was \$3.35 per ton, thus making the average working expenses \$3.80 per ton. The average yield of the ore in free gold was \$6.60 per ton.

At the meeting of the shareholders of the Sierra Buttes, the accounts showed net balance on the half year's product ending December 31, 1883, of \$43,800. A dividend aggregating \$30,625 was recommended leaving \$13,175 to be added to reserve. The amounts paid in connection with the Cross and Co. assets settlement, as the proportion applicable to the mine, have been written off, and the question has thus been finally disposed of. The mine produced 15,769 tons of ore during the half year, and the same quantity reduced by the mill. The average yield of the ore was \$7.48 per ton, and including the produce of the tailings \$8.18 per ton. The working expenses average \$5.56 per ton, the mining cost including all prospecting having been \$4.98, and the milling cost \$0.58 per ton. Excluding the cost of the eighth and ninth levels, the average working expenses would have been \$4.15 per ton. It may be mentioned that the cost of constructing the eighth level was \$51 and of the ninth \$90 per ton of ore worked.

The Action of Heat on Clinkers.

The particular objection to the combination and fusing of the silica, lime, potash, soda and sulphur in the ashes of coal into a vitreous mass is that unless the greatest care is exercised it will accumulate upon the grate bars in sufficient quantity to exclude the passage of the air necessary for combustion, and thus lower the temperature of the furnace. The several constituents of the ashes are variable in their nature, and by the forms which they take under different intensities of combustion, greatly affect the efficiency of the coals to which they belong. Being differently fusible themselves, and affecting differently the fusion of each other, no two of the earth's alkalies or metallic oxides of the ashes are alike in their agency when subjected to an elevated heat, and their mutual reactions are, moreover, changed as the temperatures to which they are exposed are changed. It hence arises that the residue from many coal-melts to a large extent under no very intense heat into various descriptions of hard and semi-vitreous slags. Others yield a less stony clinker, and some, again, at a far more elevated heat result in a partially agglutinated, spongy, open cinder, or even in a flaky ash. There are, perhaps, no coals whose ashes, when exposed to the highest temperatures procurable by artificial blasts, will not soften to a cohering cinder, or even melt in part into a stony clinker. As the tendencies, however, to these several degrees of fusion are various, it proves to be a distinction affecting the practical value of coals, which is of the utmost importance. In domestic consumption, where the heat of combustion is comparatively moderate, the quantity rather than the quality of fusibility of the ashes is the point of greatest consideration. Where, however, an excessive and melting heat is required,

Mineral Deposits of British Burmah.

Although the Burmans, as a nation, exist almost entirely by agriculture, and although the country has hitherto been little explored, enough work has been done to show that the metalliferous wealth of Lower Burmah, Upper Burmah, Karennie, and the surrounding States, is exceedingly rich and varied, so that it is doubtful whether Siam or Lower Cochinchina are much more bountifully supplied with nature's gifts. It is officially believed that were the more productive measures of British Burmah worked upon an improved European system, instead of by ancient native processes as now, the experiment would be found to pay very well in the long run, despite the higher value of labor there, in comparison with other sections of Her Majesty's Eastern dominions. Almost all the commoner known metals and minerals exist within its narrow confines, being frequently met with in quantities sufficient, apparently to be worth excavating, while—and this is perhaps the most important consideration of all—coal is found plentifully in all the chief mineral-producing districts. The geological structure of the country shows three distinct sections, nearly corresponding, it is said, with the divisions of Arkan, Pegu, and Tenasserim. The former produces limestone, coal and petroleum oil; Pegu, laterite, or brick earth, together with iron ore and manganese; while the eastern division abounds in tin, lead, gold, antimony, graphite, coal and limestone. Galena has likewise been found at Teelawlay, near the junction of the Amherst, Shwaygyin, and Salween districts, one mine of this metal having been profitably worked for some time past. Antimony is mostly found in the East Karennie hills, in Salween, and at Gaing-Ateran township, in Amherst; also in the Toungwaing mines near Moulmein, where it occurs disseminated in small grains through the rocks. From the latter mines, antimonial ore has already been extracted. In the Tavoy district some remarkably fine iron deposits are known to exist. From these large quantities of ore were formerly extracted, while, as boding well for their ultimate future, it may be added that an extensive and easily accessible coal field has recently been discovered in close contiguity. There are other iron mines at Thanzeik, now unworked, with coal in convenient proximity; while in Ava, past the British frontier, the extraordinary rich fields of Sagain are met with. It was here the late King of Burmah erected machinery for smelting and reducing ore; but although the works were of the then most approved style, nothing further has been done towards producing iron; and the people of Upper Burmah still rely upon the imported article. Here, again, coal is ready to hand. About fifty miles north of Mandalay some beds were traced by Dr. Oldham, of the Geological Survey; while comparatively recently Mr. Bryce came across large quantities in the Chindwin river, at some distance beyond the British frontier. The tin mines near Mergni are too well known to require recognition here otherwise than by name; suffice it to say that twenty-eight mines have been opened, though so far they have only been worked by Chinese immigrants in a most desultory fashion. Coal is plentiful in this place also, large workable deposits having been explored at a short distance up the Tenasserim river. Gold is produced in minute quantities at Shwaygyin, once famous for its diggings. The Thayetjundat, which flows into the Shwaygyin, brings down with it a certain amount of auriferous sand. But, unhappily, the search for the quartz reef from which the river gold is presumably derived has hitherto proved unsuccessful; nevertheless, hopes of its early discovery are still confidently entertained. However, where the best chance presents itself is in the district now being opened up by the States railways. The Irrawaddy Valley line from Rangoon to Prome intersects the rich Myamoung coal levels, besides passing within a reasonable distance of the Hensada beds. As iron ore has been traced in many places along the route of this railway, especially in the vicinities named above, there exists every natural inducement to the building up of a great industry. Moreover, the Rangoon and Toungoo line will pass through a metalliferous and carbonaceous region, and here again mining is likely to develop eventually to a large extent. Another point, however, has to be considered as bearing upon the problematical chances of these iron fields being shortly worked. Until now wood fuel has been exclusively used upon the Burmese railways, but vigorous attempts are now being made to obtain a cheap indigenous coal supply, and should the government engineers meet with the success they anticipate either in Myamoung or Hensada the neighboring iron mines are sure to come in for their fair share of attention on the part of private capitalists. In short, it would appear that, in developing the mineral resources of this province, English enterprise may find one of its best opportunities.—Iron.

the practicability of employing coal at all will often be determined by this one quality of clinkering of the ashes. In all such circumstances such coals are best, the ashes of which are of a nearly pure white color, and, with a large amount of silica and alumina in their composition, contain little or no alkali, nor any lime nor oxide of iron. In general it requires a high temperature to fuse these ingredients when taken by themselves; but the presence of oxide of iron tends to lower the point of fusion, and thus increases the difficulty.—Exchange.

Forty-five.—Something like a year ago the Bald Mountain Company started gangway 45 from their main tunnel at a point 1000 feet south of the Ruby Co's south line. The gangway was run on a course a little north of east a distance of 950 feet, at which point a shaft was sunk to a depth of 100 feet. A drift has been run to the eastward some thirty or forty feet, but owing to the amount of water encountered work was suspended and gangway abandoned. No large body of gravel was found, but gravel encountered was well washed. A fair prospect was obtained. The Lowell Avenue tunnel is eight feet lower than the lowest point reached by the shaft, which will enable them to bottom the channel with a tunnel if they desire to do so. The channel is supposed to be the same that was worked by the old Extension at Rock Creek.—Mountain Messenger.

The Sitting Bull Smelter at Black Hills produced \$63,287 in base bullion from a ten days' run. It is said that the smelter will remain idle for the rest of the season, as with the addition and improvements to the mill, all ore can be handled by the new works, which will be ready by the 1st of June.

In the Salmon River country there is nothing specially new to report, but the preparations for an active season and the prospects for it, are better than ever before.

It is said that the Homestake Mining Company of Black Hills will erect a 200 stamp mill. It was only a few years ago that a sixty stamp mill was the largest in that camp. Then came an eighty stamp, and afterwards two 120 stamp mills. The rumor indicates a permanency in mining in that section which is gratifying to note.

THE ENGINEER.

Two New Trans-Continental Roads.

It is reported that the engineering corps of the Atlantic & Pacific railroad, at the Needles, have received instructions to move their outfit across the Colorado river at once and begin operations on the line, thence through Cajon pass to Colton. It will be borne in mind that when the Atlantic & Pacific reached the Colorado river, a short time since, they were met by the Southern Pacific with a road from their Mohave station, which brought the A. & P. to a halt. If the above rumor proves true, it means that the A. & P. intend either to go to San Diego and put on a line of steamers thence to San Francisco, or that they will turn to the west, near H. J. Lomb, and reach the Coast range at or near Point Conception, and thence along the coast to San Francisco. This would form an opposition road to the Southern Pacific.

Again, it is reported that the Denver and Rio Grande, which is already at Salt Lake, thereby completely flanking the Union Pacific, have determined to continue their line from the southern point of Salt Lake westwardly direct to San Francisco. If both of these projections are carried out we shall soon have three lines in full competition for the great and growing business of California, and one of them a double line.

THE RAILWAY MILEAGE OF THE WORLD.—The following is the estimated railway mileage of the world, January 1, 1883:

Miles.	Miles.
United States.....113,000	Australia.....3,200
Europe.....109,000	Africa.....2,200
Asia.....8,000	Mexico.....2,100
South America.....7,000	Canada.....8,500
	Grand total.....253,000

These figures are not claimed to be exact. It is absolutely impossible to obtain official returns for the same period, within a year after or two after date; and so it is necessary to use the latest available statement and add the probable increase since that time. Europe and Asia are a great deal older than the United States, but the latter country has about as many miles of railway as both the former continents. If Canada's and Mexico's mileage were added to that of the United States, the aggregate would be more than the total for Europe and Asia.

BUSINESS FOR THE FLORIDA CANAL.—The proposed Florida canal, the New Orleans *City Item* claims, would secure a greater tonnage than that now passing through the Suez, or likely to pass the Panama canal when or if the latter is completed. Vessels passing through the Suez canal are now charged \$2 per ton; those passing through the Panama canal will be probably charged \$2.50, but it is estimated that twenty-five to thirty cents per ton would yield a handsome return on the capital necessary to construct the Florida canal, as there are no engineering difficulties, and on the Florida canal the tonnage passing through it would amount to 6,000,000 of tons annually. The New Orleans Chamber of Commerce has endorsed the scheme, and the *Item* believes that the capital will be secured without difficulty.

GUARDING AGAINST ACCIDENTS.—A commendable thing is now being done by the Central Pacific in equipping 7,000 freight cars and 200 engines with the Westinghouse automatic air brake. It is claimed for them that they apply themselves in case of accidents. The pressure is not put on from the engine, as is the case with the simple Westinghouse air-brake used on the passenger trains, but from a reservoir under each car. The engine prevents the pressure being applied, but let the connecting hose be broken or cut loose and the pressure from the reservoir locks the wheels by brakes. The improvement is of especial value on the mountain grades, and by making the control of the train easier, will enable greater speed to be made and be a safeguard against accidents.

A WOMAN'S KNOWLEDGE OF ENGINEERING.—A resident of Trenton says three or four years ago it was found that certain shapes of steel and iron work were required for the East River bridge, such as no mill was then making. This necessitated new patterns, and representatives of the mills desiring to bid for the work went to New York to consult with Colonel Roebling. They were greatly surprised when Mrs. Roebling sat down with them, and by her knowledge of engineering helped them out with their patterns and cleared away difficulties which had for weeks been puzzling their brains. Mrs. Roebling, a day or two since, passed over the bridge in her carriage, the first vehicle to make the transit.

WOOD RIVER is about uniting with the rest of the country in the iron bands of the railroad, the track being completed to Hailey a week or so ago, and nearly to Bellevue by this time. The mines of that country are mainly in gold, enterprising hands, and they will make a record of production this year that will give the country a hotter name than anything that has been or could be said of it.

THE SECOND SUEZ CANAL has now taken definite shape. The Company have announced that they propose to commence the cutting forthwith, and have applied to the English government for their support in obtaining the necessary concession of land from the Kedive.

USEFUL INFORMATION.

Improved Process of Making White Lead.

In the United States the manufacture of white lead, is conducted according to the Dutch method. Plates or gratings of lead are exposed to the fumes of vinegar, in vessels set in tan, or stable manure, which acts as a hot bed to warm and volatilize the vinegar. As the lead is corroded, it becomes covered with the carbonate, which is removed with hammers and ground. The process is tedious, slovenly and unhealthy, and many attempts have been made to improve it, but none of them have yielded a product equal to that which results from corrosion. Microscopically examined, the carbonate of lead formed upon the metal, is found to consist chiefly of minute crystals, which are hydrated, laminated and transparent. These are mingled with a smaller quantity of exfoliated particles of the carbonate, which are opaque. These particles, it is claimed, impart to the white lead its remarkable power of resinifying oils, as well as what the trade calls its body, i. e., its property of completely covering objects painted with it. By the new process workmen are not required to detach by hand the carbonate from metal which remains uncorroded, and the product is said to consist almost exclusively of the valuable opaque particles. To effect this, the lead is first brought to the porous or spongy form, by which the surface, exposed to the slow carbonating process, is enormously enlarged, the thin mass being seemingly composed of open interlaced fibres. This is put in a close chamber, and there exposed to a mixture of atmospheric air, carbonic acid, and the vapor of acetic acid. The carbonic acid, generated by combustion, is cooled and purified before it is driven into the chamber. The air passes in warm, and care is required to maintain the proper degree of moisture. The carbonate is the shape of the metal upon which it is formed, and the material is not removed until the corrosion is complete.

RUBBER STAMP INK.—The following proportions are said to give an excellent ink, which, while not drying up on the pad, yet will not readily smear when impressed upon the paper: Anilin red (violet), ninety grains; boiling distilled water, one ounce; glycerine, one half teaspoonful; molasses, half as much as glycerine. The crystals of the violet dye to be powdered and rubbed up with the boiling water, and the other ingredients stirred in. Another indorsing ink, which does not dry quickly on the pad, and is quickly taken by the paper, can be obtained, according to the *Papier Zeitung*, by the following recipe: Anilin color in solid form (blue, red, etc.), sixteen parts; eighty parts boiling distilled water; seven parts glycerine, and three parts syrup. The color is dissolved in hot water, and the other ingredients are added whilst agitating. This indorsing ink is said to obtain its good quality by the addition of the syrup.

VALUE OF THE SUNFLOWER.—Agriculturists claim it is the best egg producing food known for poultry, keeping them in a thriving condition, and largely increasing the production of eggs. Every poultry raiser who tries it will find that this seed is the best food known for glossing the plumage of fowls, and is almost indispensable to those who want to fit their birds for exhibition to the best advantage. The Russian sunflower is easily raised, requires very little care, can be grown in fence corners, or other places difficult to cultivate. Its production of seed is immense, yielding often at the rate of one hundred bushels to the acre. It should be planted in hills, four feet apart, any time from the 10th of May to the 1st of July. Three quarts of seed will plant an acre.

SILVERING GLASS.—Professor Palmieri has devised a process for silvering glass by means of the reducing action on the salts of silver, which is said to have the advantage of producing a very brilliant metallic deposit. When into an ammoniacal solution of nitrate of silver is poured, first a little caustic potash, and then a few drops of glycerine, the reduction begins at once; and this action is accelerated if ether or alcohol be added to the mixture. A moderate heat and darkness are said to increase the brilliancy of the precipitate, and darkness also favors the adhesion to the mirror of the deposits.

CLEANING GLASS VESSELS.—For cleaning glass vessels, Herr Muller recommends the use of quartz-sand and (especially for vessels meant to hold drinks) lead-shot, and recommends gypsum (without silicate) and marble, also bruised bones. Where it is desired to clean glass and porcelain vessels thoroughly, of organic matter, a mixture of sulphuric acid and bichromate of potash is best.

BETTER THAN HEMP.—The mescal, from which the Indians manufacture saddle blankets, is said to be better for making ropes than hemp. Thousands of acres of the article grow wild in San Diego county, says the *San*, which could be converted into ropes.

PROTECTIVE COATING FOR IRON.—A varnish composed of 120 parts of mercury, 10 parts tin, 20 parts green vitriol, 120 parts water, and 15 parts hydrochloric acid of 1.2 specific gravity, furnishes a good coating for iron exposed to the weather.

Incombustible Paper.

Mr. G. Meyer, at a recent meeting of the Societe d'Encouragement, exhibited a new paste combination designed for the manufacture of incombustible cardboard or paper of all sorts and shades. The inventor did not wish to make known at the time the chemical composition of this paste, and also of a new ink exhibited with it, as the patents that he had applied for in Germany and America, had not yet been obtained. He made known the fact, nevertheless, that asbestos was the principal thing employed in the manufacture of his incombustible paper.

He presented specimens of writing, printing, engraving, etc., made with his inks of different colors, and also showed a water-color drawing that had been submitted to the fiery ordeal of the potter's furnace. The painting had preserved all its brilliancy and the paper all its flexibility. By request, the inventor for a few minutes exposed to a gas flame a sheet of his paper, upon which he had written with ink of his composition. Neither the ink nor the paper changed. In order to demonstrate by a most conclusive test how great a heat the paper and ink were capable of withstanding, Mr. Meyer then placed a lithograph, fifteen by sixteen centimeters, between two layers of glass in a state of fusion. On removal, the paper was found to have completely resisted the action of the heat, and the engraving to have preserved all its sharpness.

ZINC PAINT FOR CAST OR WROUGHT IRON.—A process of painting, as a substitute for galvanizing, has been invented by Messrs. Nenjeau & Delaite, of Liege. It is specially intended for objects of large dimensions, which cannot well be moved, and therefore cannot well be dipped into a bath of melted zinc. The zinc, when finely powdered, is simply mixed with oil and sealer. In this way a varnish is obtained, which is applied with a brush in the usual manner. A single layer is sufficient, but two are preferable. The coated objects can be left as they are, or bronzed or painted as required.

PAPER FROM MOSS.—A new branch of industry has sprung up in Sweden lately—the manufacture of paper from moss, not from the living plant, but from the bleached and blanching remains of mosses that lived centuries ago, and of which enormous masses have accumulated in most parts of Sweden. A manufactory of paper from this material has begun operations near Jönköping, and is said to be turning out paper in all degrees of excellence, from tissue to sheets three quarters of an inch in thickness.

GOOD MEALTH.

A Household Friend—Flaxseed.

[Written for the Press by I. H.]

Yesterday one of the boys came in from a walk through the fields, with the rather alarming announcement that he had a barley-head or wild oat in his eye. The eye looked red and inflamed and could not be touched without pain. Several ineffectual attempts were made to remove the substance, whatever it might be, by drawing the upper lid back and using a soft handkerchief; but the cause of the trouble could not be reached; it had fixed itself firmly at the back of the eye-lid. Just then I remembered a hint given in some article on accidents, and acting upon it, a single flaxseed was slipped into the corner of the eye, under the upper lid, and allowed to remain there for about ten minutes. Another effort was then made to remove the intruder and with perfect success; it proved to be a grain of wild oat with a long needle-like point. Lubricated by the flaxseed it slipped out with ease, and in a few minutes the pain had entirely ceased and the eye soon recovered its natural appearance.

Then and there I resolved that I would tell the mothers who read the Press, as a similar accident may easily happen to any child at this season; and the prompt use of a safe and easy remedy may avert many serious consequences.

No household in the country should ever be without a supply of flaxseed, both whole and ground, for there is scarcely anything which can be used with greater success by the amateur physician. At least half of the ailments of little children may be traced to cold or to some disturbance of the digestive organs, and in either of these cases a flaxseed poultice is a sovereign remedy.

Pour boiling water on the ground flaxseed, stirring briskly at the same time till it is the consistence of mush, then put it into a flannel bag, previously prepared, apply it as hot as it can be borne, and cover with several folds of flannel. Let it remain until it begins to cool, when it may be replaced by another. In cases of cold on the chest, hoarseness and cough, it often acts like a charm, and also in attacks of diarrhea and pain in the bowels. I have seen a little child, screaming in agony, relieved in a few moments by this safe household remedy, falling into a quiet sleep, and awaking the next morning quite well. Its great recommendation is that it can do no harm, even if it should fail to do good, which is more than can be said of many nostrums confidently prescribed for family use.

Flax-seed tea, if properly made, is also excellent for colds and coughs, and is pleasant enough to necessitate no coaxing of the little ones. Put two tablespoonfuls of the seed into a quart of cold water, set it over the fire, and when it

begins to boil, allow it two minutes by the clock. Then strain, add the juice of a lemon and white sugar to taste. Keep it on the back of the stove where it will be warm, and give a wineglass full at short intervals.

N. B. If you think by having whole flaxseed in the house you are prepared against all emergencies, as you can easily grind it, if wanted, in the coffee mill, just try it; but I would advise you to make the experiment some day when it is not needed, and when you can afford to be laughed at by the shining little seeds as they slip through the mill intact. I have tried it!

WALNUT CREEK.

Everybody's Business.

FACTORS PRESS.—For a practical people the anomalies we eternally perpetrate and perpetuate are astonishing. Professedly we value life at a far higher rate than cash. No fine frees the murderer. We establish costly tribunals to insure condign punishment to the manslayer. Even the filcher of coin has the machinery of the law, at a vast expense, arrayed against him.

The community are agreed that the stealing of goods and the violent taking of human life should be checked at whatever cost.

In the face of all this we allow wholesale theft and murder. This, too, without deprecatory or deprecatory word.

We permit ourselves to be robbed of that which is far the most valuable of our possessions—our health—yea, we endure to be indiscriminately slaughtered by that most detestable of methods—insidious poisoning.

The value lost—disbursed in doctors' fees and drugs and funeral expenses—exceeds tenfold the amount stolen by criminals. The lives lost are tenfold the lives violently taken by convicted criminals. This insidious poisoning we idly and culpably ignore; name it diphtheria or typhoid fever; accuse Providence, excuse self. Retained are the cesspools; retained the contaminated water supply; retained the festering piles of nastiness, not from ignorance, but from sheer laziness. "My brethren, these things ought not so to be."

EDWD. BERWICK.

Carmel valley, Monterey, May 6, 1883.

SEWAGE PERILS.—Speaking of these, the *Popular Science News* has some very sensible remarks. It says: "The vast number of traps, valves, automatic plugs, bent tubes, etc., used in houses have resulted from efforts among plumbers and inventors to meet the difficulties of the situation by the first method. It may be said that some degree of success has crowned the efforts of the mechanics to obviate sewage perils, but the success has been by no means what the gravity of the situation demands. At present there does not appear to be a single mechanical appliance known which effectually, under all circumstances, affords immunity from the return of deleterious gases and disease germs into dwellings." But it goes on to say that a Mr. Mallett, a well-known chemist, has invented a device called a *germicide*, "which most admirably meets an important end. This device is very simple, and consists in placing behind the lid of water-closets a black walnut box, within which is a metallic case holding a mass of crystalline chloride of zinc. This zinc is open to a gentle flow of water, which gradually dissolves it, and it flows into the bowl constantly, night and day, sterilizing the water so that no living germs can pass." This looks very much as if it met and overcame the difficulty.

TURPENTINE IN DIPHTHERIA.—A German, who enjoys a great reputation for veracity and reliability, recommends as a new remedy for diphtheria, oleum terebinthina rectificatum. Children take one teaspoonful morning and night; adults a tablespoonful. In children tepid milk is given after it; it might also be mixed with the same. The effect of this remedy, which has of late been highly praised by different authors, is said to be really a miraculous one. Within all ready half an hour after the administration of the drug, a bright red redness begins to spread from the margin of the diphtheritic exudation, and this redness becomes generally diffused over and taking the place of the false membrane, and the disease is said to disappear within twenty-four hours without leaving the slightest trace. While this wonderful effect is said to be invariably met with when the remedy is made use of at the very commencement of the disease, those who recommend it so highly contend that it is also successful, only less rapidly, in cases that have already progressed for several days.—*Med. and Surg. Reporter*.

OVERHEATED APARTMENTS.—Dr. William A. Hammond warns against overheated apartments. He says: "An overheated apartment always enervates its occupants. It is no uncommon thing to find rooms heated in winter by an underground furnace up to ninety degrees. Fights and murders are more numerous in hot than cold weather, and the artificially heated air that rushes into our rooms, deprived as it is of its natural moisture by the baking it has undergone, is even more productive of vicious passions. It is no surprising circumstance, therefore, to find the woman who sweaters all day in such a temperature, and adds to it at night by superfluous bed clothing, cross and disagreeable from little everyday troubles that would scarcely ruffle her temper if she kept her rooms at 65°, and opened the windows now and then."

Passing Events.

The somewhat unusual activity in the mining share market attracts considerable attention just now, and there seems to be a feeling that the Comstock is going to give the mining community an excitement before long. Still, nothing has been developed yet.

Reports from the Lower California gold excitement are very contradictory, but, judging from what is made public, the region is not an attractive one for miners.

The Cour d'Alene gold excitement, which has attracted so much attention in Montana, has quieted down, and it is now believed it was started by a "crank." The mines are now pronounced "a fraud."

There is a good deal of prospecting going on down in the southern part of this State, and many new mines are being opened. At the lower end of the Carson and Colorado railroad line, there are hundreds of men roaming the hills in search of mines. Some of the old districts down that way, are showing signs of returning vigor, and no doubt some very good mining sections will result from the work now being done.

The burning of the Harrison reduction works was a sad blow to Leadville. The works will be rebuilt.

Less Nomadic.

It would seem that one factor of the increasing prosperity, from a mining point of view, of the Pacific Coast States and Territories, is the tendency which has developed for miners to be less nomadic than formerly. At one time men were rushing from place to place wherever mines were found and spending so much time prospecting, that they never developed anything or did any steady work. The roving instinct is of course inherent in the miner, but he is now more judicious than formerly, and it takes more than mere vague rumors to make him "shake the camp" and start off for new regions.

There is a growing tendency among miners, as a class, to go to work and develop claims in good districts, and the result is more prosperous mining camps and increased production. The class of men who wander about from camp to camp, doing a little here and a little there, is disappearing with the old pioneer, and prospectors now look for mines to keep, or sell at good prices—not a bottle of whisky and a mustang, as has too often happened. When placer mines were plenty this sort of thing did all very well, but quartz mining is somewhat different. We hear now of miners building comfortable cabins where they expect to live, and making up their minds to stay by their mines and the camp. They are not to be enticed away on wild goose chases by mere rumors or chance stories. After a couple of partners have sunk a 100 foot shaft and drifted a while, they do not drop the mine causelessly and let their labor go. They are, in fact, sometimes apt to work away too long. They cannot tell when a quartz mine is worked out as they could a placer claim, and they work on, hoping to strike bonanza any time.

It really seems, therefore, that the miners, as a class, are less nomadic than formerly. True, they prick up their ears when placer discoveries, such as were announced on the Yukon river, in Alaska, recently, or the other day in Lower California, Mexico, are heard of. But they wait now for confirmatory reports, and do not drop pick, pan, shovel and claim and leave for the new El Dorado. They are more content to work what they have, if it is worth anything at all. The mining areas are now larger, and the number of miners much greater than formerly. Distances are practically lessened by railroad lines, but all camps are not within the borders of a few States, as formerly. Miners content themselves with less nomadic habits, and more flourishing camps are the consequence.

Lime and Powder.

We have several times referred to the system of "blasting with lime," now being successfully worked in many English coal mines, so as to avoid danger of gas explosions from powder flash. It is found that though the lime is very useful, in many cases it will not always meet the requirements of coal working. What now seems to be wanted is a table of comparisons between the compressed lime and gunpowder, so that a miner may know how many ounces of lime are equal in power to a given quantity of powder. A paper on this subject was read the other day before the Midland Institute of Mining Engineers, by Mr. C. E. Rhodes, who gave the result of some experiments made in the Swallow Wood and Parkgate seams of coal at Aldwarke main, with the newly invented lime cartridges. The experiments commenced in the Swallow Wood seam. This seam, Mr. Rhodes explained, was of a singularly tough character, and it had heretofore been impossible to get it otherwise than by blasting with gunpowder. Record has been kept of every shot, and he was able to state that about 12 tons of coal were brought down for every pound of powder used. For the lime cartridges, 48 feet of coal was holed to a depth of three feet, six inches; eight shot holes were put in five feet apart, and the necessary time was given for the lime to take effect, the sprags were taken out, and the result was that three and one-half tons were brought down for the eight shots. Another experiment, with seven holes drilled, brought down eight tons. This showed that in some instances the lime would not take the place of gunpowder, which was much to be regretted, for some less dangerous explosive than gunpowder was much needed. Experiments had also been tried in the Parkgate seam, which had in some places a sticky top; there the lime worked better, but still would not bring down the coal so well as powder.

New Form of Amalgamator.

In the construction of pans for the purpose of amalgamating and grinding ores which have been partially reduced by stamps, or other pulverizing appliances, it is necessary to keep up a constant circulation of the pulp so that all parts may continually pass beneath the muller and the grinding shoes, so that it may be properly reduced and amalgamated, and this circulation is usually produced by means of wings or other attachments, within the pan, by which to return the pulp to the center above or below the mullers.

A patent has just been obtained through the MINING AND SCIENTIFIC PRESS Patent Agency by Geo. W. Strong and Walter L. Strong, of this city, for a new form of amalgamating pan, in which they produce a more perfect and constant circulation by means of the angles formed by the shape of the pan within which the muller revolves.

The upper part of the pan is made square in horizontal section, and it may be slightly smaller at the bottom than at the top for more perfect action, although the operation may also be carried on in a pan with vertical sides. Through the center of the pan is a hollow core or sleeve, through which projects the shaft which rotates the muller. When the muller is set in motion, the pan being charged with pulp from the battery or crusher, the current will flow radially outward until it strikes the corners of the pan where it will be arrested and thrown back upon itself from above, passing down the center and beneath the muller and grinding shoes.

In order to produce the most perfect circulation the lower corners of the pan are cut inward so as to make corner faces which are flat. This gives the bottom an outline nearly or quite octagonal, with the sides sloping upward from it, so that when the pulp flows out from beneath the shoes it strikes these faces and is thrown upward, so that there will be a strong downward current at the center, while the external current is upward. The angles of the pan interrupt the rotary and centrifugal currents and throw them back toward the center, at the top, and this produces a rapid and constant circulation of the pulp, which is thus compelled to pass constantly beneath the shoes until every part has been subjected to a thorough grinding action, and also contact with the mercury which is contained in the pan.

Improved Quartz Pulverizer.

The MINING AND SCIENTIFIC PRESS Patent Agency has just obtained for James H. Kinkead, of Reno, Nev., a patent on a new ore crusher and pulverizer of that class in which a rotary crushing disk or plate is revolved against a stationary one. The crushing plates are peculiarly ribbed or dressed. On the face of the plate are a number of ribs radiating from the center and increasing in width towards the circumference. The outer surfaces of these ribs are flat, and continue the plane of the disk. Thence they slope to the center, and their edges are also beveled. Between the ribs are formed depressions, in one of which an aperture is made corresponding with an aperture through the muller with which the hopper communicates. There is a similar muller having on its face a flat disk and a concave crushing plate provided with ribs. When the two mullers are brought together the faces of the disks are in close proximity, and also the flat outer surfaces of the ribs on the crushing plates while on account of the concavity of the two plates an interior space is provided with which the hopper communicates.

Ore is fed in at the hopper, and passes through a stationary muller and opening in the crushing plate into the central space formed by the concavity of the two plates. Power is applied to the shaft, and the crushing plate of the muller crushes the ore between its ribs and those of the other plate, and its disk grinds or pulverizes it against the other disk. The ore is finally discharged into a casing or hollow disk, having a discharge opening. The shaft may be adjusted by set screws to force the revolving parts nearer to or further from the stationary ones, to regulate the degree of fineness of the ore. The larger pieces of ore remain within the concavity of the crushing plates until they gradually work down or out nearer to the outer ends of the ribs, where they are crushed more and more, and finally ground to a powder.

The bill passed by the Provincial Legislature of British Columbia, amending the laws relating to gold and other minerals, except coal, has been disallowed by the Dominion government.

Lands Mineral in Character.

Fully ten years ago the Commissioner of the General Land Office issued instructions to the effect that whatever is recognized as a mineral by standard authorities, and is found in such quantity and quality as to render the land more valuable on this account than for agriculture, was a "valuable mineral deposit" within the purview of the Act of May 10, 1872. Rulings to this effect have been held with reference to asphaltum, borax, auriferous cement, fire clay, kaolin, mica, marble, petroleum, slate and other substances. A case has just been decided which determines that land more valuable for its deposit of limestone than for agriculture is mineral land, and subject to sale under the mining laws of the United States.

It appears that the tract in question was returned as mineral by the Surveyor General, and was withdrawn as such by order of the Commissioner of the General Land Office. Upon the petition of Bricky (claiming it to be agricultural in character), it was advertised and sold to him by the superintendent of schools for the county in which it is located. Shortly thereafter, the superintendent notified him of the refusal of the State authorities to confirm the sale, or to take any jurisdiction over the tract so long as the Surveyor General's return remained unchanged, and he was tendered the purchase money he had paid, which he refused to accept. He then applied for a hearing to enable him to show its agricultural character, which the Land Office allowed him. The testimony shows that the tract has little agricultural value, that it lies chiefly upon a precipitous mountain-side, that less than thirty acres—and these constituting several distinct parcels—are susceptible of cultivation or irrigation, and that its chief value consists in a limestone ledge, the stone of which is used as a flux in neighboring smelting works and for manufacturing lime. It seems even that the agricultural claimant at one time made a mineral location on the claim.

The Commissioner of the General Land Office decided that land chiefly valuable for limestone is not subject to entry under the mining laws, and therefore adjudged the tract in question to be agricultural, notwithstanding the ruling of Commissioner Burdett, in the case of Rolfe, that where land was more valuable on account of limestone than for purposes of agriculture, it may be patented under these laws.

The Secretary of the Interior, to whom the case was appealed, reverses the decision of the Land Commissioner, and decides that the tract is more valuable for its limestone than for agricultural purposes. The mineral claimant therefore takes it.

The large falling off in the amount of money coined this year cannot fail to attract attention. The Mint employees have apparently had a very easy time of it. The value of the coin made is not only less, but there is an equally great difference in the number of pieces coined. The amount of Double Eagles coined in the same time last year was only \$3,392,500. There were 14,361,800 cents made last year, against 11,523,900 this year. It is true the Mint have made 2,024,620 Dimes this year, against none last year, and 8,926,440 in 5 cent pieces, against 2,679,800 last year.

A SOUTHERN IMMIGRATION BUREAU.—The Los Angeles Board of Trade is considering the establishment of an Immigration Bureau, the duty of which shall be to secure for Southern California its just proportion of the sweeping tide of immigration about to set in for this coast. The following gentlemen were elected as the committee of five on immigration: Albert Brown, John F. Humphries, J. De Barth Shorb, L. J. Rose and W. H. Workman.

THERE is now in San Francisco a lady, whose presence is well worth remark. She is Prof. Mary Krom, of the Denver School of Mines, and is believed to be the only practical female assayer in the United States. She is on the coast partly for recreation and partly for mineralogical observation.

At a recent meeting of the miners of Jordan district it was resolved that \$20 worth of work shall be done on each and every placer claim of 20 acres, and \$100 worth of work on every placer claim of 160 acres, within 12 months after location, otherwise such claims shall be subject to re-location.

THE completion of the iron bridge of the Atlantic and Pacific Railway over the Canyon Diablo, in Arizona, adds another to the list of high bridges. It spans a dark gloomy gorge. The bridge is 240 feet above the water, and 541 feet long. It weighs 837,130 pounds, and it cost \$200,000.

Enlarged Issues of the Mining and Scientific Press.

It is the intention of the publishers of this journal to spare no enterprise in advancing the future interests of its readers by all reasonable and practicable methods. Among other advances, we contemplate issuing soon several extra sized sheets, especially devoted to different important localities, commencing with the Territory of Alaska.

The contents of this issue will include a well prepared map nearly the size of two pages of the Press; views of several seaports, towns, scenery and other objects of interest. This is a new land, concerning which new information is coming to hand, and its resources are just being developed. Alaska is situated on our own coast, largely drawing her supplies from our own State, and will soon become of that importance to our community which will render it to our advantage to be well posted on all that pertains to the welfare and progress of our neighboring northmen. Our map will show the numerous water courses of Alaska, the means of water communication, the harbors, etc. We shall give a description of all the mining regions so far opened, and in fact such information as is available, and will be of general interest.

Other double editions will follow shortly after, which will be devoted to the special interests of other mining localities.

All these regions possess more or less interest for California and San Francisco. We ship goods of certain kinds from here, and, from a commercial point of view alone, our interests are mutual. Moreover, the advancement of these regions does good to the whole coast, in which we are all interested.

Persons who can contribute information of special or general interest to our readers for these various issues are solicited to send the same as early as possible. If miners will send us descriptions of their mines or camps we shall be very glad to receive them.

As we make this extra effort to advance the interests of all concerned in the places named, we ask that all who can, to favor our enterprise by making the matters more widely known, and the MINING AND SCIENTIFIC PRESS more extensively patronized. The mining literature of the world is comparatively limited. Miners and scientific men especially should be liberal to assist their helpers in a line of publication, which, at best, cannot be expected to be largely profitable while doing strict justice to the highest interests it represents.

The dates of issue of the proposed extra sheets may be varied, if circumstances should demand it, but due notice will be given.

Timbering in Mines—No. 11.

The accompanying engravings show the means employed to move the heel or foundation of vertical timbers when it becomes necessary to do so. It sometimes happens that the movement of the ground cants the timbers. Again, it is sometimes necessary to swedge the timber out at the heel to get solid work. Fig. 1 shows where the wedges are driven, and Fig. 2 shows the same. Fig. 3 is a further illustration of the method of moving the timbers. The wedges are seen between the timber and side wall. The engravings are self explanatory.

SWANSEA.—The old Swansea works, which have for years been a landmark on the margin of Owens Lake, will soon cease to be. For ten days past Mr. Wheeler has had a small force at work taking down the old furnace building, preparatory to the erection of works on higher and more suitable ground. We learn from Mr. Wheeler that it is the intention of the Swansea Company to at once put up first-class smelting works of furnace capacity of thirty tons per day, with every recent improvement.—Inyo Independent.

We see by the Bodie Free Press that the Vevair Copper Works have started up. Good results are expected from the operations of this company.

An Improved Two-Wheeled Cart.

We illustrate on this page a new style of cart patented through the MINING AND SCIENTIFIC PRESS Patent Agency by Mr. Nelson Peterson, of Antioch, Contra Costa county. Of late years considerable attention has been paid to this subject, and the ingenuity of inventors has led to various constructions, having in view the same object, namely, to make a cart an agreeable and pleasant means of conveyance. The many advantages which a two-wheeled vehicle

PETERSON'S IMPROVED CART

enjoys over one with four wheels have been heretofore offset by the single obvious disadvantage of the unpleasant motion which the rider experiences as a result of the transmission of the vertical movement of the shafts (produced by the jogging of the horse) to the axle and body of the vehicle. This results as a necessity where the shafts are secured firmly to the axle, the springs likewise, and the body to the springs. None of the parts have any independence of movement. Any break in the

Figure 1.

Figure 2.

STRAIGHTENING UP TIMBERS BY WEDGING.

rigid construction of the parts will accomplish a good result. Accordingly, some have made a spring connection between the shafts and the axle, and others have placed similar devices between the springs and the body. These connections Mr. Peterson deems insufficient and unsafe. He accomplishes the result by hinging the side springs to the axle. In order to limit the movement of the springs when thus hinged, he connects their ends forward and back with the cross bars of the shafts, by means of loosely playing links and intervening metal straps. These allow the requisite independence of the springs and body, while affording a limit to their movement and giving security to the rider. The hinge joint by which the springs are connected with the axle is a model of neatness, simplicity and strength. The shafts are held above and are secured to the axle by means of side brackets, and afford a direct draft for the horse. The body and seat are supported from and by the springs above and have no connection with the shafts, which thus cannot transmit their unpleasant motion any farther than to oscillate the axle, which motion is at once counteracted by reason of the independence of the springs. The vehicle is thus rendered a comfortable and pleasant conveyance. Its entire construction is workman-like. It has no small parts to get out of order, or to rattle. It is strong and durable, and renders as good service as a buggy embodying at the same time the advantages of lightness and economy.

In England it was found that 876 separate fatal mining accidents took place in 1882, as compared to 844 in 1881; causing the deaths of 1,121 persons in 1882, as compared to 954 in 1881; increase in separate fatal accidents, 32; increase in loss of life, 172.

Industrial Exhibition of Mechanics' Institute.

The Mechanics' Institute will open its Eighteenth Industrial Exhibition at the pavilion on Larkin street, Tuesday, Sept. 11th, and it will not close until Saturday, October 13th.

The year promises to be a memorable one to this State, and particularly to this city, on account of the large number of visitors who intend to take part in the Triennial Conclave, of Knights Templar, occurring in the latter part of August. During their sojourn here they will desire to see and learn all that is possible regarding the products and industries of this coast, and will naturally look to this fair for much information and to find the best of the farm, the workshop and the studio. Those who exhibit will have an extraordinary opportunity to show and explain their articles.

In order to stimulate production and invention, and give suitable recognition to meritorious exhibits, there will be awarded, as set forth in the premium list, gold, silver and bronze medals, diplomas, and certain sums in money.

It is the intention of the management to have the exhibition of machinery in motion especially complete, thus enabling visitors to witness the actual production or manufacture of various articles, an exhibit both interesting and instructive. To that end it is expected to have in operation wood-working machinery, for the preparation of wood for building and other purposes; iron-working machinery of the most perfect kind; agricultural machinery and implements for the farm and household; looms for weaving fabrics of wool and silk; boot and shoe machinery, mining machinery, hydraulic machinery, including the largest and most improved steam pumps; apparatus showing the advancement in electrical science; new and novel application of wind power, and many other mechanical inventions of interest and value.

The display of natural products will embrace cereals, fruits and vegetables; and on account of the increasing importance of viticulture, it is expected that the exhibit of grapes and native wines will be large and include all varieties.

For the first time in a number of years the department or mineralogy will be represented,

The Bullion Output.

The Mint Directors' report for 1882 will be issued shortly. It will be a volume of about 600 pages, giving in detail the output of each State, Territory and mine in the United States. It shows a decrease in the production of gold bullion for the year amounting to some \$2,000,000. The principal decrease was in California, where it amounted to \$1,000,000, and in Dakota. There was a small increase in Colorado. There was a large percentage of increase in the mines of the Appalachia range. The mines of Georgia showed an increase of fully 160 per cent, and those of North Carolina gave seventy per cent. The aggregate output from these mines is small, but the increase is so marked that it is expected at an early day to be of considerable importance. The product of silver for the year showed an increase over the previous year of \$2,000,000. The principal increase was from the output of the Wood River district, in Idaho, and the Lake Valley district, in Mexico. The mines of Nevada and Colorado pretty nearly held their own. For the first time in the history of the country there was a shipment of silver bearing ores from North Carolina. In the opinion of the officials of the Mint Bureau, based upon recent investigation, the mines of the Carolinas, Georgia and Virginia are attracting the attention of capitalists who will develop them to a degree unprecedented, and it is believed profitably.

The following tables give the estimate made of the bullion product of California and Nevada, made by the Director of the United States Mint. The product of this State has fallen off, owing to the hydraulic mines not all being at work. Still, the estimate given for Nevada county seems very small indeed:

CALIFORNIA.		
COUNTIES.	Gold.	Silver.
Alpine	\$20,000	\$10,000
Amador	1,500,000	
Butte	650,000	
Calaveras	670,000

Washoe	10,000	17,000
Totals	\$2,376,000	\$8,750,000

THE SILVER PLATED COPPER WIRE hitherto employed soon rubs off and the unwelcome disagreeable red color of the copper makes its appearance in spots here and there. M. M. Comte and De Bary Kroess have used the aluminum alloyed with silver to avoid this difficulty. We learn from the Polytechnisches Notizblatt that Troeltsch and Damschman in their lace factory at Weissenburg, made use of nickel which had been deprived of its brittleness. Fleitman and Witte, of Iserlohn, made the discovery not long since that the addition of a small quantity of other metals would render the nickel so ductile that it could be drawn out into wire of the finest numbers and be scarcely inferior to copper.

MICROSCOPIC INSCRIPTION OF PHYSIOLOGICAL MOVEMENTS.—M. Marey has invented an instrument which enables him to make an exact record of the phenomena of circulation, respiration, and muscular and nervous actions. By employing a fine steel point and a thin layer of lampblack, movements which do not exceed one tenth of a millimeter (.004 in.) are magnified to great dimensions. The apparatus can easily be carried in the pocket.—Comptes Rendus.

GOLD MOUNTAIN.—Guy Thorpe has completed his arrangements for reducing ores in his arrastras at Gold Mountain, in the southern part of Esmeralda county, near the State line, and was to have started up on Thursday last. He has about 15 or 20 tons from three or four different mines, which will be worked as a test. There is an abundance of water and plenty of wood on hand.—Eureka Sentinel.

Metallurgy and Ores.

Nevada Metallurgical Works,

No. 23 STEVENSON STREET,
Near First and Market Streets, S. F.
ESTABLISHED, 1869. C. A. LUCKHARDT, Manager.

Ores Worked by any Process.
Ores Sampled.
Assaying in all its Branches.
Analyses of Ores, Minerals, Waters, Etc.
Working Tests (Practical) Made.
Plans and Specifications furnished for the most suitable process for working Ores.
Special attention paid to Examinations of Mines, plans and reports furnished.

IMPORTERS OF AND DEALERS IN

Assayers' Materials,

MINE and MILL SUPPLIES,

CHEMICAL APPARATUS AND CHEMICALS, DRUG
GISTS' GLASSWARE AND SUNDRIES, Etc.

118 and 120 Market Street, and 15 and 17
California St., San Francisco.

We would call the attention of Assayers, Chemists,
Mining Companies, Milling Companies, Prospectors, etc.,
to our full stock of Balances, Furnaces, Muffles, Crucibles,
Scorifiers, etc., including, also, a full stock of
Chemicals.

Having been engaged in furnishing these supplies since
the first discovery of mines on the Pacific Coast, we feel
confident from our experience we can well suit the de-
mand for these goods both as to quality and price. Our
New Illustrated Catalogue, with prices, will be sent on
application.

Our Gold and Silver Tables, showing the value per
ounce Troy at different degrees of fineness, and valuable
tables for computation of assays in grams and grammes,
will be sent free upon application. Agents for the Patent
Plumbago Crucible Co., London, England.

San Francisco Pioneer Screen Works J. W. QUICK, MANUFACTURER.

Several first premiums received
for Quartz Mill Screens, and Per-
forated Sheet Metals of every
description. I would call special
attention to my SLOT CUT and
SLOT PUNCHED SCREENS,
which are attracting much at-
tention, and giving universal
satisfaction. This is the only
establishment on the coast de-
voted exclusively to the manu-
facture of Screens. Mill owners using Battery Screens exten-
sively can contract for large supplies at favorable rates.
Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Ships and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Grant and Old Abo Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Dug's Mechanical Atomizer or Pulverizer.

For reducing to an invaluable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BAUVES, COAL

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weight 6,500 lbs.; heaviest pieces, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

THOS. F. ROWLAND, Sole Man'fr, Brooklyn, N. Y.

JOINT FOR SHEET METAL PIPE.

RE-ISSUE PATENT NO. 8,214 TO JOSEPH MOORE AND FRANCIS SMITH.

"The invention consists in connecting the meeting ends of the pipes firmly together and placing a hard or tube around the outside of the meeting ends, which is larger in diameter than the pipes, and which is long enough to extend a distance on each side of the joint and thus filling the space between the outside band or tube and the pipe, with a packing of lead or other soft material, either by casting or tamping."—[Extract from specification of Patent.]

These joints have been tested for 8 years, and are undoubtedly the best joint made for sheet iron pipes—THE BEST AND CHEAPEST.

Any INFRINGEMENT will be PROSECUTED.

FRANCIS SMITH & CO.,
Manufacturers of Pipe of all Kinds,
130 BEALE ST., SAN FRANCISCO.

IMHAUSER'S

Watchman's Improved Time Detector,
WITH SAFETY LOCK ATTACHMENT.

(Patented 1875-6-7-80-81.)

Beware of imitations. This instrument is supplied with 12 keys for 12 stations. Invaluable for all concerns employing night watchmen. Send for Circulars to

DUNHAM, CARRIGAN & CO.,
San Francisco, - - California

FLORNOY'S ANTI-SCALE COMPOUND FOR STEAM BOILERS.

Will effectively rid of scale any steam boiler, and, as long as used, prevent its accumulation. Especially recommended to parties owning THRESHING MACHINES. Is entirely free from acids, acting as a preservative of the iron and a lubricant. Is recommended by the "Scientific American" as the best known. Has been used in the U. S. Mine of San Francisco for the past two years. Send all orders to

GEO. FLORNOY, JR.,
220 1/2 McAllister St., - - San Francisco
George Flournoy of the firm of Flournoy, Moon & Flournoy, Attorneys-at-Law, above address.

LORD'S

Boiler Cleansing Compound,

For the prevention and removal of Scale in Steam Boilers, and for Neutralizing Acid, Sulphur and Mineral Waters.

Important safeguard and remedy for all users of steam. For Circulars and all information regarding same, please apply at office of the Agents.

From the official list of U. S. Patents in Dewey & Co.'s Scientific Press Patent Agency, 252 Market St., S. F.

- FOR WEEK ENDING MAY 22, 1883.
- 277,979.—BED OR PILLOW.—Blockman & Evans, S. F.
- 277,982.—AGRICULTURAL MACHINE.—A. Bradford, Dallas, Or.
- 277,989.—WATER JACKET FOR FURNACES.—John H. Canavan, Globe, A. T.
- 277,991.—SPOKE EXTRACTOR.—R. N. Coughell, Shedd, Or.
- 278,004.—SOFA-BED.—B. F. Farrar, S. F.
- 278,123.—WATER HEATER.—H. A. Gantert, S. F.
- 278,010.—PUMPING APPARATUS FOR DEEP WELLS AND MINES.—J. H. Huffer, Jacksonville, Or.
- 278,240.—LIFE PRESERVER.—Geo. P. Hunt, S. F.
- 277,902.—SWING.—Walter Hyde, Oakland, Cal.
- 278,243.—LUBRICATING COMPOUND.—H. E. Lepper, Carson, Nev.
- 278,151.—TRACTION ENGINE.—L. F. Lillard, Dixon, Cal.
- 278,160.—DRY ORE SEPARATOR.—J. C. McCurdy, S. F.
- 278,035.—AMALGAMATOR AND SETTLER.—Fred. Morris, S. F.
- 278,044.—WIRE ROPE RAILWAY.—W. S. Ray, S. F.
- 278,045.—SEWER TRAP.—Geo. A. Reich, S. F.
- 278,189.—BALL COCK.—Wm. Smith, S. F.
- 278,059.—AMALGAMATOR.—G. W. & W. S. Strong, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of special mention:

CABLE RAILWAY.—Wm. S. Ray, S. F. No. 278,044. Dated May 22, 1883. This consists in a novel construction of the ropeway and of the gripping apparatus by which the car is connected with the rope, whereby the car may be propelled around curves, or made to cross other cable lines without interfering with them. This is effected by the use of an independent moving device which is placed in the upper part of the cable tube or tunnel where the curve or crossing is to be made, and a mechanism secured to the grip, which will engage with this device when required, the rope or cable being depressed so as to be entirely out of the way at these points.

SOFA BEDS.—B. F. Farrar, S. F. No. 278,004. Dated May 28, 1883. The improvements consist in the means for hinging and adjusting those parts or portions which are intended to fold up or open out—as, for example, the back or heads. The object is to provide a simple and effective means for operating the hinged parts and sustaining them in any desired position.

SPOKE EXTRACTOR.—Robert N. Coughell, Shedd, Oregon. No. 277,991. Dated May 22, 1883. This invention relates to a new and useful device for removing spokes from the hub, and it consists in a peculiar clamping ring fitting the spoke and acting as a lever, and having a fulcrum on the hub, and a means for applying the power at the outer side.

THE Dry Creek bridge below the town of Healdsburg was partially destroyed by fire last week.

FRANCIS D. MOULTON has struck salt near Warsaw, in New York. The well is located on the Rochester and Pittsburgh Railroad, midway between Warsaw and Leroy. Salt was found at a depth of 1,150 feet.

A DEVIL FISH measuring eight feet in circumference, was captured at Santa Monica a few days ago.

WEAK muscles and nerves, sluggishness of thought and inactivity, cured by Brown's Iron Bitters.

ORE PULVERIZER.—The rotary ore pulverizer, advertised in another column as for sale by Mr. Heald, has been used but very slightly, and is a bargain to any one in want of such a machine. It is only sold because the company which ordered it is dissolved, and there is no possible use for it. All the necessary gearing, frame, etc., go with the pulverizer, which can be set running in half an hour after it is received. Parties needing something which will grind ore fine, will do well to communicate with Mr. Heald concerning this machine.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

- G. W. McGREW—Santa Clara county.
- M. P. OWENS—Santa Cruz county.
- J. W. A. WITTEN—Merced, Tulare and Kern counties.
- JAMES G. HOGG—California.
- B. W. CHOWELL—Arizona Territory.
- S. H. HARGOOD—Plumas county.
- M. H. JOSEPH—Kearney, Nev.
- I. M. LEHR—Los Angeles, San Bernardino and San Diego counties.
- A. G. KNOX—Oregon and Washington Ter.
- F. W. STRUTTON—Sierra and Yuba counties.
- J. BARRERA—Yolo county.
- J. W. HOWE—Sacramento county.

Amalgamating Plates.

We saw this week at the silver plating works of E. G. Denniston in this city, five very large amalgamating plates for a mill in Colorado. These are the largest heavy plates that have ever been plated, they being five feet by eight feet—forty square feet of surface on each. The plating is done on heavy copper, and is a very creditable job indeed. The preparation of silver-plated amalgamating plates for catching amalgam, gold and silver, has now become quite an extensive business, and Mr. Denniston having been the pioneer in this line, has built up quite a reputation and trade, shipping his plates all over the country. He has a bath 8 feet long, 6 feet deep and 3 feet wide, specially for these large mining plates. The establishment is now the most extensive one in the United States on this kind of work. They are now filling orders in every direction and competing successfully with Eastern parties. Mr. Denniston has lately enlarged his works, and is now putting in a 25-horse power engine and boiler. The engine is a Westinghouse, made in Pittsburgh, Pennsylvania, by the Westinghouse Machine Company. The works are branching out and will soon have power and room to let. They are very busy now, and mining plates particularly are in demand. Gold, silver and nickel plating in every variety is done. The many years' experience in these lines which Mr. Denniston has passed through enables him to do his work with skill and satisfaction. The personal supervision he exercises over the various departments is one of the prominent factors in the success of the establishment.

A New Bergstrom Organ.

Bergstrom & Co., of this city, have recently finished the construction of a very fine large organ for the First Methodist Church of Oakland. It combines all the very latest improvements, and its exterior finish is of rich but neat design. The upper section is open, exposing the large diapason pipes, which are tastefully decorated in gold and colors to harmonize with the frescoing of the church.

The organ proper is divided into great, swell and pedal, each of which may be operated separately, or all coupled into one. It is provided with two banks of keys, of four and one-half octaves each, and two octaves of pedals. There are 18 stops, as follows:

Swell organ—Oboe, bassoon, flautina, flute traverso, stop diapason, viola treble, viola bass, trumpet and tremolo.

Great organ—Fifteenth, twelfth, flute harmonic, octave, melodia, open diapason.

Pedal organ—Cello, contron.

General—Bellows signal, three sets of couplers, great forte, great piano (the last two worked by the foot), and swell.

The stops of the great and swell organ work directly upon 58 notes each, and those of the pedal upon 27.

The stops are so arranged as to give immediate and distinct response, and Mr. Sam'l Mayer, one of our most skilled organists, speaks highly of this feature. The couplers are adjusted between the manuals, and consist of three sets of two each, one to couple and the other to uncouple, the effect being produced in either case by a mere pressure of the thumb or a finger, which can be done without raising the hands from the keys. These couple the swell and pedal, the great and swell, or the great and pedal. The pedal couplers connect the entire great organ with the pedals, or shunt it off, as the case may be. The swell organ is controlled by the foot, and is so arranged as to remain at any point of swell the operator desires, and without the necessity of securing the pedal. Thus the wing may be entirely closed, slightly opened, half opened, or fully opened, and the foot withdrawn without disturbing the effect. This also is a novel contrivance.

A Backus' water motor is to be supplied to furnish power. The air is first taken into one large bellows, and thence is distributed to six smaller ones, working independently, from which the air presses into the pipes by the action of the stops.

Messrs. Bergstrom & Co., makers of this fine instrument, have an extensive factory in this city where various styles of organs are made. They have supplied many of the churches and Sunday schools of this coast with organs. Mr. Bergstrom has introduced many features of his own invention in the instruments and they are highly spoken of by all who have heard them. This particular organ has an excellent tone, and at both the public and private exhibitions it was commended both by experts and amateurs.

PROF. J. G. LEMMON and wife expect soon to make their summer botanizing excursions to Arizona. Until July their time will be spent mostly in the canyons of the north side of the mountain ranges, where the climate is more comfortable than on the plains. After the early rains, which usually prevail in July, they will leave their wilder mountain camps for the more propitious fields for botany below. The rapidity with which the verdure and flora of the plains spring up and grow after the warm rains is said to seem almost marvelous. We trust our readers may often hear from these faithful devotees of a noble calling, and whom we hope will return in health in due season, with stores of good success.

VIGOR, strength and health all found in one bottle of Brown's Iron Bitters.

News in Brief.

EIGHT THOUSAND emigrants, mostly Mormons, have passed through Hull, England, the past few days for America.

GOVERNOR STANFORD has sent Wild Flower, Hinda Rose, Bonita and five colts to be entered for the Chicago races in July.

THE Northern Pacific Railroad Company has men out in the field examining and appraising land in eastern Washington Territory.

THE once despised lands of Nevada are being rapidly taken up. The sales by the State Land Office since last January have been about 6,000 acres per month.

WHILE riding up the Suislaw River, near Eugene City, Or., the accidental discharge of a gun in the hands of G. Harper killed his son, who was by his side.

THE ship George S. Homer arrived at Portland, Or., yesterday, from New York, 116 days out. She used auxiliary steam thirty days and passed through the Straits of Lemaite.

THE Lower California gold excitement is fizzling out. The gold shipped from there was sold by Indians to Mexicans, and there is no accurate knowledge of when or where it was found.

AN 1,800,000-acre purchase of land in the Panhandle of Texas, by an English syndicate, is reported. The price paid was \$3,000,000. The tract will be fenced. It borders thirty miles on Indian Territory.

At a meeting of the miners of Bear Mountain district, New Mexico, it was decided to call the new camp "Fleming." Miners' wages in the district are \$4 per day.

NORTH BLOOMFIELD GRAVEL M. Co.'s bonds, to the extent of \$50,000, will be redeemed on the 21st. The mine continues to pay largely.

Recent Contributions to the California State Mining Bureau.

[Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY G. HANKS, State Mineralogist.]

[CATALOGUE.]

4885. Red Porphyry—Rome, Italy. J. S. Hittell.
4886. Green Porphyry—Rome, Italy. J. S. Hittell.
4887. Limonite after Pyrite—Red Hill, Butte Co., Cal. A. B. Paul.
4888. Murex Indivia. Recent Shell, Japanese Waters.
4889. Mineral Coal, used by the natives as an ornament, probably water-worn fragments from the sea beach—Siberian shore of Behring Straits. George Balser.
4890. Crude Copper, product of the Soda Springs smelting furnace—Esmeralda Co., Nev. J. D. Crossman.
4891. Fossiliferous Limestone—Siberian Coast of the Arctic Ocean. George Balser.
4892. Zircon Sand—Hydraulic mine, Irish Hill, Amador Co., Cal. J. W. Loomis.
4893. Volcanic Ash—Tone Valley, two miles from Lone City, Amador Co., Cal. J. W. Loomis.
4894. White Marble—Nine miles north of Lone City, Amador Co., Cal. J. W. Loomis.
4895. Pyrite—Yellow Jacket mine, Esmeralda Co., Nev. C. O. Og.
4896. Durangite—A very rare mineral found in lodes of tin in the mines of Coneto, Durango, Mexico. J. Z. Davis.
4897. Anthracite (?) Coal—Queen Charlotte's Island, British Columbia. M. Toomey.
4898. Copper Ore—Near Romama, Los Angeles Co., Cal. C. F. Allen.
4899. Copper Ore—Ingomar mine, near Luning, Esmeralda Co., Nev. J. H. Crossman.
4900. Pyrolucite—Alameda Co., Cal. Rev. Mr. Briggs.
4901. Chalcedonic Quartz—Dry Creek, six miles northeast of Lone City, Amador Co., Cal. J. W. Loomis.
4902. Talc—Near San Quentin Bay, Lower California, Mexico. J. A. Morales.
4903. Chromite Iron—Near Livermore, Alameda Co., Cal. W. Martin.
4904. Stibnite, Sulphide of Antimony—Paintmill Valley, Inyo Co., Cal. George K. Philips. This deposit has long been known, and may be found located on Atlas Sheet No. 65, D. Wheeler's Atlas, Geographical Surveys and Explorations west of the 100th meridian.
4905. Pyrite—Clipper Coal mine, Lincoln, Placer Co., Cal. John Landis.
4906. Pebbles—Found beneath the coal (No. 4905), Clipper Coal mine, Lincoln, Placer Co., Cal. John Landis.
4907. Bog Iron Ore—Found five miles from Alameda, Alameda Co., Cal. Dr. S. G. George.
4908. Obsidian, variegated—Near McBride's ranch, Mono Co., Cal. J. M. Graham.
4909. Peeten Fossil—Sandstone Bluff, township one north, and on Humboldt meridian, Humboldt Co., Cal. J. M. Graham.
4910. Shell Rock—Sandstone Bluff, township one north, and on the Humboldt meridian, Humboldt Co., Cal. J. M. Graham.
4911. Jeffriesite—Tulare Co., Cal. Wm. H. Randall.
4912. Silver Ore, very rich, showing Cerargyrite—Queen mine, Colton District, San Bernardino Co., Cal. J. Daggett.
4913. Kaolin (pure, prepared)—Worcester Royal Porcelain Works, England.
4914. Pure Porcelain Clay, baked—Worcester Royal Porcelain Works, England.
4915. Fire Clay—Worcester Royal Porcelain Works, Eng.
4916. Clay—From Nevada City (No. 4220-1), baked in a common sewer pipe kiln by Gladding & McBean, who say if it was properly washed and otherwise prepared, it would be equal to the best kaolin.
4917. Fossil Horse Bones—Desert east of Silver Lake, Lake Co., Oregon. John Daggett.
4918. Necklace—A plant which grows on Pitcairnia Island, and worn as an ornament by the women of that island. John Daggett.
4919. Tapa, or Native Cloth of the South Sea Islanders, in five stages of manufacture. John Daggett.
4920. Wood, from which tapa (No. 4919) is made—South Sea Islands. John Daggett.
4921. Water, two galleons—From Goose Lake, Modoc Co., Cal. F. H. Merrill.
4922. Gold Quartz—Gaugre mine, section 32, township 2 north, range 14 east, in the town of Tuttleton, Toluima Co., Cal. George R. Wilson.
4923. Trochus Magnus, Upper Pliocene Fossil—Hills of Asti, Alessandria, Northern Italy.

Failing!

That is what a great many people are doing. They don't know just what is the matter, but they have a combination of pains and aches, and each month they grow worse.

The only sure remedy yet found is BROWN'S IRON BITTERS, and this by rapid and thorough assimilation with the blood purifies and enriches it, and rich, strong blood flowing to every part of the system repairs the wasted tissues, drives out disease and gives health and strength.

This is why BROWN'S IRON BITTERS will cure kidney and liver diseases, consumption, rheumatism, neuralgia, dyspepsia, malaria, intermittent fevers, &c.

Mr. Simon Blanchard, a well-known citizen of Hayessville, Meade county, Kentucky, says: "My wife had been sick for a long time, and her constitution was all broken down and she was unable to work. She was advised to use Brown's Iron Bitters, and found it to work like a charm. We would not now be without it for any consideration, as we consider it the best tonic in the world."

BROWN'S IRON BITTERS is not a drink and does not contain whiskey. It is the only preparation of Iron that causes no injurious effects. Get the genuine. Don't be imposed on with imitations.

PELTON'S PATENT

Reaction Hurdy Gurdy Water-Wheel.

This Wheel will be guaranteed to purchasers to give 8% of the theoretical power of water. As sold for Charles L. A. PELTON, Nevada City, Nevada Co., Cal.

BAKER'S MINING HORSE POWER.

THE MOST EFFICIENT AND PRACTICAL MACHINE ever invented for the service of Prospectors and others, requiring the use of a Horse Power 14 possessing all the requirements of a first-class hoist and offering means for the continuous operation of a Pump or Blower without interfering with a hoisting apparatus.

It is made entirely of Iron; no piece weighs over 250 pounds. At the ordinary speed of a horse a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting drum is under the complete control of the man at the shaft, and is capable of carrying 500 feet of five-eighths steel rope. The cost of erection is slight, as two men in half a day can easily put it in place ready for work.

While this power is more particularly for mining purposes, it is equally adapted to all other uses where animal power is required. SEND FOR CIRCULAR. Address

MINERS' HORSE-WHIM

One Horse can easily hoist over 1,000 pounds at a depth of 500 feet. The whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The standard of the whim is bolted to bed-timbers, thus avoiding all frame work. When required these whims are made in sections to pack on mules.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,
—OR—
VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

EXCELSIOR BLASTING POWDER.

Manufactured by the

EXCELSIOR POWDER COMPANY.

This is no new, patent, non-explosive Safety Powder, but the Genuine Standard Nitro-Glycerine Powder, as safe to use and handle as any other Nitro-Glycerine Powder manufactured. The fumes, as are common in nitro-glycerine powders, are destroyed, and do not leave the miner with headache or nausea.

The powder is put up in cartridges of any size to suit the consumer, and is exploded in the same manner as all other high explosives; that is, by means of cap and fuse, or by electricity. It is not claimed for this powder that it is a non-explosive, or safer than other nitro-glycerine powder. All powder, and especially nitro-glycerine powder, should be handled carefully. The EXCELSIOR POWDER is as safe, and for strength far surpasses any other powder on the market. Address all orders to

EXCELSIOR POWDER COMPANY,

Room 9, No. 3 California St., San Francisco, Cal.

IMPROVED FORM — OF — HYDRAULIC GIANT

We call the attention of those using or interested in Hydraulic Mining Machinery to the above out of an improved form of Hydraulic Giant, in which it will be observed that the Deflector and heavy weighting rear part are abolished and a lever attachment, working with a ratchet and pawl substituted, by which the pipeman, standing in the rear of the machine, has, without danger of "bucking," full control of the direction and effect of the stream. In an action in the U. S. Circuit Court, entitled F. H. Fisher and Joshua Hendy vs. Richard Hoskins et al. of the Marysville Foundry, a permanent injunction has recently been ordered against all persons manufacturing or using any form of Hydraulic Machine having the equivalents of the above.

All of the usual sizes are manufactured (under an exclusive right) and for sale at reduced prices by JOSHUA HENDY, at the

JOSHUA HENDY MACHINE WORKS,

49 and 51 Fremont Street, San Francisco, Cal.

ANTI-SCALE COMPOUND

Manufactured by RICKARD & DURDEN.

VOLUME XLVI
Number 23.

New Pumping Apparatus for Mines.

The engraving on this page illustrates a new form of pumping apparatus designed by John H. Huffer, of Jacksonville, Oregon, who has patented his device through the MINING AND SCIENTIFIC PRESS Patent Agency. The shaft of a mine is represented with stations at various levels, where pumps are placed. At the surface of the ground, and across the mouth of the shaft is mounted a shaft upon which is secured a pulley. Extending from each of the various stations or levels are short shafts, each carrying double faced pulleys, all of which are here in a vertical plane with the pulley at one side of the shaft.

Clamped upon top of the face of the upper pulley is a flat cable or belt, the ends of which pass over the sides of the pulley and hang down in the shaft. The cable may be a flat wire cable, or a chain, as may be necessary. Clamped to the tops of the next two pulleys, upon their outer faces, are similar flat cables or belts, the ends of which hang down on each side.

Under the three pulleys, upon their inner faces, are clamped flat cables, the ends of which extend up over the sides of the pulleys, and are connected with the depending end of the flat cables alongside of them respectively by round cables or chains, or cords, thus completing the connection between all the pulleys so the oscillation of the driving pulley will oscillate the other three. Tightening nuts and turn buckles take up the slack.

To produce the oscillatory movement a steam engine cylinder is mounted on the surface, and in a frame are two rods or tracks, upon which a traveler is adapted to reciprocate. The end of the piston rod of the engine is connected with this traveler to which it transmits a reciprocating rectilinear motion.

Secured on the shaft is a pulley with three faces. A band or belt is clamped on top of the central face and thence passes loosely around one side of it and under the pulley, and is secured to the end of the traveler nearest the steam cylinder. Two similar bands or belts are clamped to the outer faces, thence pass loosely around and under the pulley in an opposite direction to that of the central band, and are secured to the opposite end of the traveler. Through these bands or belts the rectilinear reciprocating motion of the traveler is converted into an oscillatory movement, with which the pulley is affected. Through the shaft and pulley all of the other pulleys are oscillated. The movement is reconverted into a rectilinear reciprocating motion affecting the pump rods. There are frames and tracks in said frames, and reciprocating travelers at each station where there is a pump.

Secured upon each of these shafts are pulleys having three faces. Bands or belts are clamped upon these faces and pass loosely around them, being secured to opposite ends of the travelers, the arrangement being similar to those of pulley and traveler above. Thus the oscillating movement of these pulleys is transmitted to the pump rods in a rectilinear reciprocating motion to operate the pumps. There are no racks or pinions.

These pumps are supposed to be double-acting pumps, and are connected with each other through suitable pipes and intervening tanks, or in any appropriate manner. Vertical pumps may be also worked on exactly the same principle, with a little different arrangement. One ver-

tical pump is shown in the engraving. The inventor states that this conversion of rectilinear to oscillating motion, and vice versa, while being simple, is advantageous in overcoming the dead-center of crank motion for one half of a circle.

Although the engraving shows the pumping

lating pulley, connected through belts and chains with an oscillating driving pulley receiving motion from an engine or a hand-crank, as might be desirable.

The operation of the lift pump has a tendency to throw the system out of balance by the amount of force required to operate it. This

HUFFER'S MINE DRAINING APPARATUS.

apparatus in a shaft of a mine, it is obvious that the same apparatus is applicable to a deep well. In all ordinary cases of this character no stations would be required other than the one near the bottom, where the pump would be supported. This could be in any practicable manner. The principle on which the well pump is operated is shown in the smaller of the two engravings accompanying this article; the details are arranged to suit circumstances. The pump-rod would be reciprocated in the manner already described by the oscil-

PUMP ARRANGED FOR WELL.

may be overcome by adjusting the cut off of the steam engine, allowing it to admit more steam at one end than at the other. When the required depth of shaft is reached, the lift pump may be dispensed with. This apparatus will work at any angle desired by fastening the chains or cables at the center of the pulleys on a line in the new direction. By the use of this apparatus the power is exerted directly against the water to be lifted, less the friction on the bearings, and the inventor is confident there will be no jar in pumping.

Coal Lands and School Sections.

Some little time since, certain miners applied to the U. S. Land Office, to enter certain coal lands in Washington Territory, but the Commissioner of the General Land Office refused to accept the money for the lands, because the land applied for was reserved for the purpose of being applied to the common school funds, under the law establishing the Territorial government of Washington. From this decision the miners appealed to the Secretary of the Interior and, as all the papers were regular, the only question presenting itself was: "Is the land subject to entry under the coal Act?"

On March 22d, 1853, "Congress" passed a law declaring that "sections 16 and 36 in each township of Washington Territory, shall be reserved for the purpose of being applied to common schools in that Territory." The Secretary of the Interior holds that this was a reservation, not a grant, as no granting words were used. The title remained in the United States and the sections remained subject to future disposal of the Government.

These sections then being simply reserved for school purposes and not granted, and the Government having parted with no control over them, it was undoubtedly competent for Congress, in its discretion, to make any other disposition of them it might deem advisable, under whatever conditions it might deem proper.

Therefore, when Congress in 1866, 1872 and 1873 established a system for the disposal of its mineral lands, a system differing widely from all other methods of disposal of public land, a system which provides in terms that mineral lands should be disposed of under its provisions and in no other way, the conclusion is natural that whatever may have been the Congressional intent at the time of the passage of the act of 1853 (at which date the existence of minerals in Washington Territory was unknown), it underwent considerable modification before 1866 and finally in that year signified its changed purpose by the Act of 1866, followed by those of 1872 and 1873.

The Secretary is of the opinion that Congress intended the mining Acts to apply to all public lands of the United States shown to be mineral in character. It is the settled policy of Congress to except from all grants and reservations to State, railroad or other persons all mineral lands in whatever sections the mineral may be found. That such is the policy of the government appears to be very definitely settled by the case of the *Ivanhoe* vs. *Keystone*, recently decided by the Supreme Court of the U. S. In this case no exception on account of the mineral character of sections 16 and 36 could be found in the language of the Act granting said sections to the State of California, yet nevertheless the court held that "Congress did not intend to depart from its uniform policy, i. e., of reserving mineral lands, in this respect in the grant of those sections to the State."

If this principle applies in case of a grant, it would certainly apply with at least equal force to a reservation where the title never passed out of the government. The Secretary concludes, therefore, that mineral land in these sections was reserved from the reservation for the Territory of Washington, and was designed for disposition under the mining statutes of the United States.

FRANK BROTHERTON is running the leaching works of George Nicoll & Co., of San Antonio.

Mining Dividends.

The New York mining papers keep lists of dividend-paying mines standing, and run them from issue to issue, indefinitely. But no two of them are alike, either as to mines or amounts paid, and none of them are complete. The Salt Lake *Tribune* gives a list, as full as it can make it, and suggests that some of the papers in the States and Territories concerned take the trouble to verify the amounts given, and to add such as may be wanting to make a complete list. It will be understood, of course, that there are many mines in all these States and Territories owned by corporations, or by individuals, or firms, which have realized great profits and divided them without any publicity. A case in point is that of the Emma, which, before the mine caved in and otherwise fell into litigation and troubles and perplexities of various kinds, sold 26,651 tons of ore for \$2,581,408. Out of this take the cost of mining, hauling, sampling and selling, which could hardly have exceeded \$15 or \$20 a ton, or, at the outside, \$581,508, and the \$2,000,000 would be profit, and might have been disbursed as dividends. The Flagstaff, well and honestly managed, must have shown an equal or greater profit. Some of the Bingham mines, as the Old Telegraph, the Spanish and the Jordan, which have turned out 50,000 or 60,000 tons of ore each, must have realized a profit of \$10 a ton; and so, in proportion, of the Miller, what is now the Joab Lawrence, the Grizzly and Lornia, Davenport, Prince of Wales, Reed & Beison, Eclipse, Florida, Hidden Treasure, Queen of the Hills, Mono, and some of the mines of Star district. It is hardly likely that the dividends actually declared and paid by Utah mines represents more than one-third, or certainly one-half, of the profits realized from the business during the last twelve years. With these preliminary remarks to indicate what is doubtless as true of other mining States and Territories as it is of Utah, we submit the following lists, arranged from the New York papers.

Richmond Con (est.).....	5,000,000		
Total.....	\$138,594,400		

The gross output of Nevada must be nearly three times this sum—say \$350,000,000. The Comstock alone has produced \$240,000,000; Pioche, perhaps \$20,000,000; Eureka, \$50,000,000; White Pine, \$10,000,000; and other districts the rest of it, \$30,000,000. The total of assessments on Washoe mines is about \$72,000,000; other Nevada mines, \$10,500,000; California mines, \$5,572,000; Idaho mines, \$920,000;

Dakota mines, \$865,000; Arizona mines, \$440,000; Utah mines (Leeds), \$87,000; about \$91,000,000. Against this there is a total output, easy, of \$500,000,000. But, of course, the assessments levied do not represent all the money that has gone into the business, probably not more than ten per cent on the whole. The gross output in twenty years of California, Nevada, Arizona, Utah, Idaho, Colorado and Dakota, and Montana would push \$1,200,000,000 very hard, and probably not more than one third of this was net.

Smelting Ores.

It is not generally known, but still it is nevertheless a fact, that as fine prospects for first-class smelting ores are to be found in Mazourka canyon, opposite Independence, as in any other part of the Inyo range. The Union district has been greatly neglected and overlooked by what few mining men who have visited Owens valley. The idea has got abroad, and it has been fostered by certain parties, that all the good mines and prospects are situated in the southern portion of the county; but this is a mistake, as can be easily proved to any well posted mining man who will take the trouble to spend a day in examining the prospects in Mazourka canyon, under the guidance of a man who is familiar with the locations. It is true that but little work has been done on the claims in this particular section, where the lead ores are mostly found, but that little has shown up as encouraging prospects for good mines as can be found in any other mining district in the State. This statement is based on the opinion of men who have had many years of practical experience in smelting ores, and who have thoroughly examined the district a number of times. The facilities for cheap mining and smelting are unequalled in any other part of the Inyo range, being very accessible, with an unlimited supply of wood for cheap charcoal close at hand, and the mines only about six miles from Independence, and two miles from the railroad and Owens river. The particular section referred to embraces about four miles in length by one mile in width, within which is located some ten or twelve claims, in a formation between limestone, granite and quartzite. An immense ledge, running north and south, with brown iron oxide croppings, which can be seen from a distance of several miles, contains the lead ores above mentioned. On the north end of this belt or ledge is situated the Eagle mine, which shows a fine vein of smelting ore, carrying about forty per cent of lead and forty ounces of silver per ton. This mine has been prospected some, and about thirty tons of ore are now on the dump. Want of means, and some way of selling or smelting the ore, stopped the work. The next claim on the south of the Eagle is the Tubal Cain, showing a vein of lead ore three feet wide, assaying fifty ounces of silver, five dollars in gold, and forty per cent of lead. About thirty tons of this ore has been taken out and now lies on the dump. The ore is a dark brown carbonate of lead, carrying a good percentage of iron, which adds to its value as a smelting ore. This mine is within 300 yards of a good wagon road. The next claim on the south of the Tubal Cain is the Mabel and Emma, with the same character of lead ore, but of a higher grade in silver. A shaft thirty feet deep has been sunk on this mine and considerable ore taken out. Joining on the Mabel and Emma, still south, is the Oneida mine, with two shafts, showing a vein three feet wide, and the same ore as the other claims. The above are only a few of the many good prospects in Mazourka. Many others could be named, showing rich gold and silver ores, which in any other country would create an excitement. It certainly seems strange that parties coming into this valley to look for mines will not even go to look at prospects that any one competent to judge must pronounce valuable when once examined.—*Inyo Independent*.

SINCE the discovery of the Lake Superior deposits, the copper mines of the United States have, until recently, yielded a sufficient supply to meet the demand for home consumption, leaving, also, a large surplus for export.

Thoughts on Prospecting.

A Plain Talk by an Idaho Paper.

The following article, taken from the Bellevue (Idaho) *Chronicle*, will doubtless be read with a great deal of interest by many of our miners and prospectors. It is a correct view of the matter, and doubtless is the experience of every mining town on the coast. We give the article in full:

Mining is of more interest to the *Chronicle's* readers at this particular time than any other topic, so that a plain talk must be permitted to miners and others interested in mines. We do not wish to speak disparagingly of any man's prospect. We know the earth abounds in the highest grade ore to be found in any country. No matter what others may wish to say against Bellevue—no matter how eagerly they wish to speculate in town lots in other places—not a word has been uttered derogatory to our mining resources. We want to be understood at the start, and then the observations made will be taken in the right sense. There are too many prospects held by men who wish to realize a fortune from the mere prospect. A man digs a hole in the ground twelve or fourteen feet in depth and strikes a good deposit of ore. He lays aside his shovel and pick, asks an enormous sum for the evidence he has of the existence of ore, and from that onward does nothing more on the prospect than the law requires. His prospect may be a good one, and with development it may be made a paying mine. But it costs thousands of dollars to develop a prospect into a paying mine, grafting the ore holds out. Owners of prospects must bear the fact in mind that a prospect is not a silver mine. If these prospective mines could be purchased at reasonable figures, it is thought that about 100 would change hands inside of one week in the vicinity of Bellevue alone. Perhaps five men would be put to work upon each one of these claims. In addition to these men already working mines, we would have 400 or 500 more. It would not take long with such a force to develop our mines and start a general boom that would benefit both business men and miners. About four years ago, it will be remembered, a great mining excitement prevailed at Bonanza, Idaho. Prospectors held valuable prospects, and many could have realized fair fortunes from them; but capitalists could not afford to pay extortionate figures for mere prospects. The result is, nearly every one of these prospectors still own their claims, which are practically worthless, and years of time has been lost in waiting for something to turn up. The bird in the bush is still at large.

Of course Bellevue is not like Bonanza, but this matter of holding prospects at enormous prices will have the same effect on the owners. It will have a tendency to concentrate the mining energy into a few of the leading mines, and prospects will remain as such till the owners are as gray as rats. Much depends upon mines falling into lands prepared to work them. To this end, for the good of the prospectors, we suggest that the moral of the Bonanza story be heeded. Realize every cent you can for your property, but it will pay better to sell it than to take the risks incident to the vicissitudes of a mining country.

Gold, Silver, Copper.

Yavapai county, says the Prescott *Courier* is justly celebrated for her rich mines, which hold in place shiploads of the precious metals and unmeasured quantities of the useful ones. Until very recently, shipments of the precious ones have not been very large. Old style mills, erected mainly to work quartz for free gold, were not very successful. Their partial failure gave the county a sore eye, from which it is now fast recovering. Our first quartz men thought of nothing but gold, of which they found a great deal in some ledges. It is but a few years since men discovered that, with the gold, silver was in close communication. Now it is silver and gold. Silver is predominant in all our mines. It is the metal that flows from the Lynx creek smelter in a steady stream, that makes the Silver Belt, the Black Warrior, the Peck, the Alta, the Congar, the Tiger, and the scores of other mines valuable. What makes our silver mines more valuable than those of other localities is the fact that gold is associated with the whiter metal, making the value of our bullion much higher than it would otherwise be. We have just learned, after many failures, how to mine and reduce ores, and nothing can now retard the progress of the country.

Another advance was made when our prospectors discovered ores carrying copper in paying quantities. The mines of Castle creek district, south of Prescott, were, we believe, among the first to make this fact plain. Then came C. C. Bean's discoveries and developments in Copper Basin, near Prescott, where there are acres of copper.

started up a few days ago, has, every day, run out, six tons of copper, which is entirely free from arsenic and antimony. This copper is shipped to Phelps, Dodge & Co., New York City. The Copper Mountain and the Copper Queen mines are, so far, the only ones in Arizona which produce the free metal. As the mine promises to last for many years, we may safely conclude that, to Mr. Stoddard's foresight, sound judgement and economical business habits are our citizens indebted for another paying mine and successful smelter.

The Waterwheel Trials

The test of the Reaction Hurdy-Gurdy Water Wheels at the Idaho mine has been completed some time, says the *Foothill Tidings*, and the result has just been given to the newspapers for publication. The tests commenced on April 30th and continued, in public, until all of the competing wheels had a fair and impartial trial. The Pelton wheel came out victorious, according to the figures, and we believe that all of the competitors conceded that the Pelton was the best wheel. This test at the Idaho will doubtless be the means of establishing the Pelton as the wheel to be used generally. Mr. George G. Allan, at his foundry in Nevada City, is now busily engaged in the manufacture of these wheels, he having orders from all over the State.

In making the tests a prony brake was used on wheels 6 feet in diameter, under a head of 386 feet and 6 inches, the point of connection with the scale beam describing a circumference of 30 feet. In measuring the water to ascertain the cubic feet per minute discharged, a thin plate weir, without contraction, 3 feet and 1/2 inch long, was used, and the J. B. Francis formula for discharge of water over weirs, was adopted as the basis of the calculations. These were made by Mr. George Fletcher, Auditor of the Narrow Gauge Railroad Company, and were as follows:

PRESCOTT WHEEL.				
Weight on brakes, lbs.	Revolu- tions.	Horse- power.	Head of water over weir, inches.	Cubic ft. of water per minute.
444	196	79.2	4.975	163.211
358	290	84.2	4.975	163.211
361	246	80.8	4.975	163.211
339	276	84.4	4.975	163.211
295	281	76.1	4.975	163.211
358	259	84.3	4.975	163.211

Other tests were made of this wheel resulting in an average of \$2,925 horse-power, utilizing 69.6 per cent of the force and impact of the water.

PELTON WHEEL—FIRST TEST.				
Weight on brakes, lbs.	Revolu- tions.	Horse- power.	Head of water over weir, inches.	Cubic ft. of water per minute.
465	254	107.58	4.975	163.211
465	255	107.97	4.975	163.211
400	256	107.05	4.975	163.211
400	256	107.29	4.975	163.211

SECOND TEST.				
Weight on brakes, lbs.	Revolu- tions.	Horse- power.	Head of water over weir, inches.	Cubic ft. of water per minute.
465	256	108.43	4.950	162.98
470	249	108.30	4.950	162.98
490	257	107.68	4.950	162.98
465	254	107.37	4.950	162.98

LOWER NOZZLE.				
Weight on brakes, lbs.	Revolu- tions.	Horse- power.	Head of water over weir, inches.	Cubic ft. of water per minute.
465	257	107.47	4.950	162.98
469	254	107.58	4.950	162.98

STILL LOWER.				
Weight on brakes, lbs.	Revolu- tions.	Horse- power.	Head of water over weir, inches.	Cubic ft. of water per minute.
465	253	106.95	4.950	162.98

HIGH NOZZLE.				
Weight on brakes, lbs.	Revolu- tions.	Horse- power.	Head of water over weir, inches.	Cubic ft. of water per minute.
495	256	108.21	4.950	162.98
465	249	106.26	4.950	162.98

Average horse-power, 107.49, or 9.2 per cent.

KNIGHT WHEEL—FIRST TEST.				
Weight on brakes, lbs.	Revolu- tions.	Horse- power.	Head of water over weir, inches.	Cubic ft. of water per minute.
430	217	84.8	—	152.60
400	232	84.36	—	152.60
400	236	85.8	—	152.60

The cubic inches of water in this test were reckoned on the amount of miner's inches used, allowing 1.40 cubic feet per minute for one miner's inch. This shows 77.18 per cent of the power of the water.

SECOND TEST.				
Weight on brakes, lbs.	Revolu- tions.	Horse- power.	Head of water over weir, inches.	Cubic ft. of water per minute.
490	241	100.78	5.325	180.72
475	204	88.00	5.100	109.35

Average per cent of first test 76.5. Average per cent of second test 71.2. These were the only tests made of this wheel, the nozzles breaking and having none other on hand.

TAYLOR WHEEL.				
Weight on brakes, lbs.	Revolu- tions.	Horse- power.	Head of water over weir, inches.	Cubic ft. of water per minute.
400	184	69.91	4.975	163.211
312½	254	72.16	1.975	163.211

MECHANICAL PROGRESS.

Seasoning Wood.

Wood requires time in which to season very much in proportion to the density of the fiber. But this rule is not without an exception, for pitch pine, which is not at all a densely fibered wood, requires a long time in which to season, even when the process is conducted under favorable conditions. This occurs in consequence of the resinous character of pitch pine, the resin clogging the pores of the wood and thus stopping up the channels through which the moisture would otherwise exude. There are some woods—and mahogany, ebony, and some other of the tropical woods, are of the number—that even in their living state contain very little moisture.

Plants that are of slow growth contain less moisture, when in a living state, than do those whose growths are rapid. A mahogany tree requires 500 years in which to mature, and as a consequence, its texture is exceedingly dense. Being dense in texture, it requires a long time in which to season, and during that lengthened period it shrinks very little. Mahogany should not be kept longer than necessary in the log, because inasmuch as the outside portion of the log contains the greatest amount of moisture, and it being the exposed part, it will, as the wood dries, shrink more than the inner wood, and so, to allow for the outside shrinking, outside shakes will and must occur. The same remark applies with equal force to all log timber, but we name the circumstance in connection with mahogany particularly, for the reason that it is a general practice for some to keep their mahogany logs for a long time in an unseasoned state.

WHAT IS GALVANIZING?—In reply to an inquiry as to the meaning of the word "galvanizing," as applied to iron that has been coated with zinc, the *Manufacturer and Builder* replies that the word so applied is a misnomer, and is misleading to many, who naturally infer that it refers to an electro-deposited coating, as it should do, from the derivation of the word. This journal adds:

There is, nevertheless, some ground for the name, as the protective action of the zinc in shielding the underlying metal from oxidation is partly an electrical or galvanic one. Thus, at the points of contact of the two metals, (iron and zinc), in the presence of moisture a galvanic action is set up, in which the zinc as the electro-positive element of the couple is oxidized, the iron as the electro-negative element being protected. The iron thus coated will remain uncorroded for a very long time. To bring this protective influence into prominence, it will be well to contrast the behavior of tinned iron (made in a similar manner by immersing cleaned iron into a bath of molten tin). Here we have also two metals in contact; but in the presence of moisture they behave very differently from zinc-coated iron. Here, too, a galvanic action takes place between the two metals at the exposed points of contact, whenever moisture is present, but the conditions are reversed. In this case the iron is the electro-positive element, and the tin the electro-negative one; and it is the iron that is oxidized while the tin is preserved. Hence the necessity of painting tinned iron (such as roofs) wherever it is exposed to the weather, as otherwise it would be more rapidly destroyed by corrosion than if the iron were exposed alone, the galvanic action between the two metals serving to facilitate the oxidation of the iron. The name "galvanized," as applied to zinc-coated iron, is, we believe, of French origin, the process, according to Dr. Ure, having been originally patented in France.—*Mechanical News*.

ELECTRICITY.—Indications are multiplying that the electric motor will ere long be substituted for steam upon local railway lines in large cities. At least a vigorous attempt will be made to apply it in that manner, and the question will be settled, for the time being, whether it is a practical and economical agent. Hitherto the examples of its use have been merely interesting scientific experiments, and have left unsolved the great problem of profit and loss, which is the point on which its destiny hinges so far as railway managers are concerned. There is now a strong probability that the electric motor will be practically tested on one of the elevated railroads in New York; and a tunnel railroad under the Thames, in London, is shortly to be built, the trains on which will be drawn by electric engines. Nothing remains to be determined in regard to this motive power, to insure its general introduction, except the vital question, whether it will pay. The other advantages possessed by it are sufficiently obvious to render the public impatient for its speedy and thorough trial.

WET AND DRY COAL IN MAKING STEAM.—A series of tests were made recently at Bochum, Germany, to determine the value of wet and dry bituminous coal in the making of steam. Washed slack, holding 18 per cent of water and 9.9 per cent of ash, evaporated 5.7 pounds of water per pound of fuel; while the same coal, with only three per cent of water, made from eight to 8.5 pounds of steam. Making due allowance for moisture by reducing to a standard of like quantities of coal, free from moisture, there is found to be a direct loss by using wet coal of 14 per cent.

Grading Pig Iron by Grain.

An interesting circumstance which demonstrates the possible error arising from grading pig iron by fracture has been investigated by Mr. Ernest Sjosdelt, chemist of the Shelby Iron Co., Alabama. The *Journal of the United States Association of Charcoal Iron Workers*, in referring to the matter, says that a lot of iron had been selected by the grain only, and graded as Nos. 1, 2 and 3. When remelted and chill tests taken from it, the No. 2 iron showed a deeper chill than either No. 1 or 3, and deep enough for a No. 5 iron.

The practice at Shelby Iron Works is to grade all car-wheel iron by the chill plate, as follows:

Grades of car-wheel iron: No. 1 and 2 show no chill in pig; No. 3 chills one-fourth inch; No. 4 chills one-half inch; No. 5 chills three-fourths to one inch; No. 5½ chills three-fourths to one inch with the air chill; No. 6 mottled; No. 7, white; iron is also assorted by grain.

Poundry iron: No. 1 X, very open grain and soft; No. 1, open grain and soft; No. 2 medium grain; No. 3, close dark gray.

Mr. Sjosdelt made partial analysis of the pig iron of each grade, and the chill tests taken from them are as follows:

No. 1 pig iron contains 1.042 per cent silicon; the chill test, 1.040 per cent silicon.

No. 2 pig iron, .511 per cent silicon and .612 manganese; chill test (a), .486 per cent silicon, and .576 manganese; chill test (b), .495 per cent silicon, and .535 manganese.

No. 3 pig iron, .920 per cent silicon, and .540 manganese; the chill test, .749 per cent silicon.

What was graded as No. 2 pig iron, therefore, corresponded in its chemical constituents with a Shelby No. 5 (the average amount of silicon of which is .65 to .45 per cent), and, as the manganese is neither unusually too high nor too low, and the surface of the pig has all the appearance of a high grade iron (being much more honeycombed than sample No. 3), the fact of its high chill is quite natural.

The No. 2 pig iron was selected on account of its open grain, it showing a fracture between Nos. 1 and 3.

A DIFFICULT THING TO UNDERSTAND.—One of the most difficult things to make an ordinary mechanic understand is that two things cannot occupy the same place at the same time. It is consequently a never ending source of wonderment to him when he finds that lace, a gelatine film, or a pressed flower, can be made to give an impression in lead, or even in soft steel, when passed between the rollers of a transferring press. That the soft substance can indent the hard one taxes his credulity to the utmost, and when he sees the work done he is ready to disbelieve his own eyes. When such a man finds the print of a hair on his cold forging, or a thousand and one other instances illustrating this fact that two substances cannot occupy the same space at the same time, his wonderment exceeds all bounds, and yet, though slow to believe such a demonstration as this, it is easy to accept the fact that a little water on the piston may be sufficient to smash the cylinder or blow off the head, which is only another illustration of the same fact.—*Mechanics*.

NEW ZEALAND IRONSAND.—Ironsand works for the manufacture of iron sand into iron have recently been completed at Onehunga, on the west coast of New Zealand. There are scores of miles of iron sand in that colony, but notwithstanding the high percentage of iron which the sand contains, all attempts to render remunerative the manufacture of iron from it have hitherto failed. Excellent steel has been produced from the sand, but the process of manufacture was found to be too costly. Recently, however, machinery has been imported from the United States, and it has been found that, with the aid of this machinery, the sand can be worked cheaply. Mr. W. H. Jones, formerly of the Rockaway Ironworks, New Jersey, has been appointed manager to the new Onehunga works. It is proposed at present to manufacture only bars and iron wire, but the manufacture of hoops, sheets and plates is to be undertaken. The plant on the ground at present consists of a furnace 32 feet in height, a reverberatory puddling furnace with a deoxidiser over it, in which the sand is deoxidised by the waste heat from the puddling furnace, and a separator. The iron sand is brought by sea from the Manukau Heads, and is, in the first instance, taken to the separating shed, where, by the aid of magnets, the iron is separated from the other foreign matter and they fall into separate shoots. The iron sand contains from seventy to seventy-five per cent of pure iron after the separating process, but it is estimated that five per cent is still left in the refuse, which is partly beach sand, with a small percentage of titanium. The iron sand thus cleansed is then hoisted to the top of the furnace, into which it is introduced by a number of small openings into a series of retorts, where it is subjected to heat, causing the oxygen to be expelled from the iron, thereby reversing Professor Bardi's invention of coating iron with black oxide. After the expulsion of the oxygen, the sand is in a wrought metallic state. Upon opening a valve any required quantity of red hot sand is run into the puddling furnace, where the carbon is burnt out of it, after which the iron is treated as in an ordinary puddling furnace, blooms being taken from the furnace and finished.

SCIENTIFIC PROGRESS.

Some Examples of Chemical Synthesis.

But a few years ago the determination of the exact composition of a body was regarded as the highest application of chemistry. Especially was this the case when the body was organic. To separate it into its elements, bring them into forms to be weighed, and ascertain their precise quantities and proportions, was the most refined process of the chemist's art. That he should combine these elements, and with them create bodies similar to those belonging to the organic kingdom, was regarded, even by the fathers of the science, as too much to hope for. And yet, that is just what is being done to-day. The application of the processes of analysis brought chemistry much renown, and made it an exact science. By the application of the processes of synthesis, the chemistry of the laboratory usurps the functions of the chemistry of vegetation, and creates the important products of agriculture, madder and indigo, out of their elements. The study of chemical synthesis is, therefore, incumbent on the student. Let us take one of Mr. Edison's incandescence lamps as mounted and ready for use. The fine bow of carbon within the glass globe is in the midst of a vacuum. Now let us surround it with an atmosphere of hydrogen, by admitting that gas pure and dry, seal and put the lamp in circuit. If the electrical current is strong, the carbon will glow for a moment and then disappear. It has combined with the hydrogen and formed a hydro-carbon, which is aciform and transparent, therefore invisible. By means of well known tests, this aciform compound is proved to be acetylene, the composition of which is equally well known. In order to form it, the atoms of carbon and of hydrogen have arranged themselves in twos, thus: C₂H₂. Carbon and hydrogen, members of the mineral kingdom, have united to form acetylene, an organic body and a constituent of illuminating gas. Now, as acetylene can be converted into olefiant gas, C₂H₄, and then into alcohol, C₂H₅O, it follows that alcohol and its numerous derivatives may be classed among the products of the chemical synthesis. But they by no means comprise the only class. Were we able to heat the globe containing the acetylene, and maintain it at nearly the fusing point of glass, the molecules of acetylene would, so to speak, form themselves into groups of three, which may be represented thus, C₂H₂.C₂H₂.C₂H₂, or, more briefly, C₃H₃, which is benzol, the most important of all the components of gas tar; the point of departure of a host of valuable organic products, including aniline and indigo. The force which coerced the molecules of acetylene into uniting to form benzol, was heat, and the atoms of carbon and of hydrogen were also combined by the intense incandescence of the carbon. The incandescence was caused by a current of electricity, but had it been produced equally by any other cause, acetylene would have been formed. The phenomenon was not electrical, but calorific.

By synthetic chemistry, the gas tar products, represented by benzol, naphthaline, and anthracene, may be converted into the petroleum products, and the relation between the two classes having thus been established, the question whether they are, or are not mutually convertible, at once arises. Fortunately for the great petroleum interests of the country—fortunately for the manufacturers and consumers of artificial dyes—the question is settled in the affirmative. The waste product of the Russian petroleum refineries in the Caucasus, has been there converted into anthracene, and from this anthracene the "Badische Anilin und Soda-fabrik" at Ludwigshafen, manufactured alizarine and sent it to the Moscow exhibition. Naphthaline, which yields magdala red, Martin's yellow, and naphthylamine blues and violets has also been obtained from the residuum in the petroleum stills, and benzol as well, which yields indigo and the group of aniline colors. Such are some of the results directly traceable to the study of chemical synthesis.—*From a lecture by Dr. A. L. Kennedy*.

LIGHT FROM GAS.—The amount of light given out by a gas flame depends upon the temperature to which the particles of solid carbon in the flame are raised, and Dr. Tyndall has shown that of the radiant energy set up in such a flame, only the one twenty-fifth part is luminous; the hot products of combustion carry off at least four times as much energy as is radiated, so that not more than one-hundredth part of the heat evolved in combustion is converted into light.

SEPARATING CITRIC AND TARTARIC ACIDS.—C. Rovera contributes the following to the *Giornal Farm. Chim.* A solution which contains both acids is neutralized with sodium carbonate, and then boiled to expel the carbonic acid. To this is added enough of the original solution of the two acids to make it distinctly but faintly acid. Then a solution of calcium chloride is added, and this precipitates all of the tartaric acid. The filtrate from this precipitate contains calcium citrate, which separates if the solution is boiled.

HOW TO BRIGHTEN CARPETS.—After the dust has been thoroughly beaten out of carpets, and they are tacked down again, they can be brightened very much by scattering cornmeal mixed with coarse salt over them, and then sweeping it off. Mix the salt and meal in equal proportions.

Formation of Arsenides by Pressure.

Spring has continued his experiments on the formation of chemical compounds by simple pressure, and now gives the results obtained with arsenic. When zinc filings and pulverized arsenic, mixed in the proportions required by the formula Zn₃As₂ are submitted to a pressure of 6,500 atmospheres, a homogeneous metallic-like block is obtained, crystalline under the microscope, and brittle under the hammer. It dissolves completely in sulphuric acid, evolving hydrogen arsenide and leaving only a small black residue. A similar mixture of lead and arsenic gives a homogeneous block of metallic luster, hard and brittle, and which does not clog the file. The arsenide of tin corresponding to the formula Sn₃As₄ thus obtained, is a white metallic mass, brittle with foliated structure, fusible at a higher temperature than tin, and difficultly soluble in hydrochloric acid with evolution of H₃As. The cadmium arsenide required three pressings, and gave a brittle metallic mass. No compound of as high a composition in arsenic, Cd₃As₂ could be formed by fusion. Copper combines with arsenic under a pressure only with difficulty. After eight pressings a homogeneous metallic mass resulted, brittle and granular, grayish-white in color. Silver acts similarly, giving a bluish-gray homogeneous metallic mass. Arsenic itself, when submitted to 6,500 atmospheres, acquired a metallic luster and a specific gravity of 4.91.—*Ber. Chem. Ges.*

FORMATION OF CHEMICAL COMPOUNDS BY PRESSURE.—Mr. Spring, the German chemist whose experiments on the formation of solids by pressure were recorded in our columns some time since, has continued his researches, and now gives some of the results obtained. He found that when zinc filings and pulverized arsenic in proper proportions are submitted to a pressure of 6,500 atmospheres, a homogeneous metallic-like block is obtained, which appears crystalline under the microscope and brittle under the hammer. It was found to dissolve completely in sulphuric acid, evolving hydrogen arsenide, and leaving only a small black residue. A similar mixture of lead and arsenic gave a homogeneous block of metallic luster, hard and brittle, and which does not clog a file. Arsenide of tin obtained in this manner is a white metallic and brittle mass, with foliated structure, fusible at a higher temperature than tin, and dissolving with some difficulty in hydrochloric acid. The arsenide of cadmium was submitted to pressure three times, and gave a brittle metallic mass. Copper was found to combine with arsenic under pressure only with difficulty, and after having been submitted to the operation some eight times a homogeneous metallic mass was obtained, brittle and granular and grayish-white in color. Silver was found to give a similar mass, being of a bluish-gray color and homogeneous in structure. Arsenic itself, when submitted to 6,500 atmospheres, acquired a metallic luster and a specific gravity of 4.91.

NEW AND STALE BREAD.—A celebrated French chemist, M. Boussingault, has recently been investigating the nature of the change which takes place when bread becomes stale, something which has hitherto not been understood. In the course of his experiments, a circular loaf 12 inches in diameter, and six inches thick, was taken from an oven heated to 240° Reaumur, and a thermometer forced into it three inches. The thermometer indicated 78° F. (207.5 F.). The loaf was then taken to a room, the temperature of which was 15° R. (66° F.), and found to weigh seven and a half pounds. In 12 hours the temperature of loaf sunk to 19° R. (73° F.), and in 24 hours to 15° (66), and in 36 hours to 14° (63.5). In the first 48 hours it lost only two ounces in weight. After six days the loaf was again put in the oven, and when the thermometer had indicated that its temperature had risen to 55° R. (156 F.), it was cut open and found to be fresh, and to possess the same qualities as if it had been taken out of the oven the first time; but it had lost twelve ounces in weight. Experiments were made with slices of bread with similar results, proving conclusively, that new bread differs from old, not by containing a larger proportion of water, but by a peculiar molecular condition. This commences and continues to change during cooling, but by again heating the bread to a certain temperature, it is restored to its original state. It is the mechanical state which makes new bread less digestible than old. The former is so soft, elastic and glutinous in all its parts, that ordinary mastication fails to reduce it to a sufficiently digestible condition.

LUMINOUSITY OF THE MAGNETIC FIELD.—Professor W. F. Barrett, of Dublin, has been making some interesting experiments to test the correctness of the discovery claimed to have been made by the late Baron von Reichenbach, viz., that a peculiar luminous effect, resembling a faint electric discharge in rarefied air, emanated from the poles of a magnet, and was rendered visible in a perfectly darkened room.

COOKING.—A Montreal firm has invented and patented a machine for cooking by electricity. It consists of a saucepan so isolated by non-conductors that the bottom forms the positive pole of the current. The negative pole is attached to a movable point which travels in circles over the bottom of the pan underneath, distributing the heat over the whole surface and with sufficient rapidity to avoid burning a hole through the pan at any one point.

THE DEADWOOD SHAFT.—*National*, May 29: On Monday we paid a visit to the new works at this shaft, now owned by the California Prospecting Co., and under the management of Mr. E. L. Parsons. The shaft was put down some years ago by the original owners of the Deadwood channel, and a small drift or two runs, and then, through some complications, the engine used in the work was taken away, and of course the work had to be suspended. The ground yielded richly for the amount of labor performed, and it now seems to be in a fair way to be thoroughly opened and worked. A nice little engine is running, which pumps the water and does the hoisting easily. Mr. Parsons has shown considerable ingenuity and mechanical skill in fitting up the mine. The shaft is 68 ft in depth. The "pump" is simply a rubber belt, to which tin buckets are attached every three feet. The endless belt runs into a "sump" at the bottom of the shaft, where the buckets fill and when they arrive at the top, pass over a drum or roller and discharge into a flume which takes away the water. The convenience is novel in shaft-working, but perfectly simple, and highly satisfactory. It is not necessary to run it more than half the time to keep the mine dry. The other compartment is fitted up for a cage, on which the cars, filled with gravel are run, and hoisted to the top, where they run to the washing-dump, conveniently situated, just below the hoisting works. Work has but just commenced in the drifts, and no returns have yet been made, but there is no chance for a failure, as the ground is known to be good, and the channel for many hundred feet has never been bottomed except by this shaft. Messrs. Miller and Flynn handle the engine, and Mr. P. Trayner is the foreman of the mine.

CLAREMONT HILL.—No news of much importance comes from Claremont, except that the prospecting work is being pushed vigorously and every day adds evidence to the fact that a rich and extensive gravel mine is there. The tunnel has developed the pay-gravel for more than one hundred ft across the channel, and it is said to equal in appearance anything to be found in the blue gravel channels of Sierra county. The owners are satisfied with the prospects, and will now put up buildings, etc., for permanent work. No gravel can be washed at present, as there is no lumber for flumes, but the pan and rocker prospects gold in quantities sufficient to prove that Claremont is solid. The hill will be a busy place for years to come, and furnish employment for a large number of men.

San Bernardino.
GOMBLER.—*Calico Print*, June 2: Considerable advancement has been made in this mine within the last few weeks. Besides the clearing away of surface earth on the bluffs, and at the same time taking out a large quantity of good ore, a shaft has been sunk to a depth of 50 ft on the ledge from which ore is being taken, a tunnel has been driven in on the ledge from the south 30 ft, and another on the north, 12 ft. A large quantity of fine ore is taken from these tunnels, keeping a car busy running the ore out to the chute.

BISMARCK. The working force on this mine has been increased to eight men. Work in the shaft is progressing in the midst of good ore. It is Mr. Godfrey's intention to sink the shaft to a depth of 50 ft, then cross-cut and stope ore.

SNOW BIRD. The new cuts recently made in the hill are looking well, the veins opened up getting broader and the quantity and quality of the ore increasing. Out of the numerous veins that can be seen running through the hill there is a likelihood that a permanent ledge will be struck, of which they are lewders. The Coleman Co., who recently bought several borax deposits a few miles east of Calico, have a dozen men at work taking out the borax and shipping it to San Francisco.

Sierra.
RICH BOWLER.—*Mountain Messenger*: A very rich quartz boulder was found in the Nevada claims at Gibsonville, a few days since. The boulder was found lying close to the surface, and weighed 165 pounds. It is estimated to contain over \$2,000. Fifteen hundred dollars was offered for it, but the offer was refused. Cox, Denoon and Gourley are the owners of the claim. The Rainbow company, Chippis Flat, has done remarkably well during the last two weeks, the output of gold going away up into the thousands. The owners are reticent in regard to the yield, but it has undoubtedly been larger than outsiders are aware of.

GIBSONVILLE.—The Union company are still taking out excellent pay, although they are bothered some with water. The company's tunnel is in over 4,000 feet. Unfortunately they were about 30 feet too high, and are obliged to work through an incline. Water has increased so fast that the company has let a contract at \$125 per week to keep the mine free from water. Gravel and water are both raised by hand as yet, which renders the working exceptionally expensive. For the past month and more the gravel has paid in the neighborhood of six or seven dollars per carload. The North American company now has its tunnel clear through the ridge, and has found gravel that pays \$2.25 per load, which is good pay, considering that the mine is not an expensive one to work, as mines go.

EXTENSION.—The Extension company took out 78 ounces and 10 pennyweights of gold last week, the value of which was \$1,460.10. The company are working 18 breasters. More cars are being made as rapidly as possible. The company are now working three miles to haul their gravel, and the workmen to and from their work, a little over 4,000 feet. A connection by 12-inch pipe has been made with the Bald Mountain works at Lowell avenue, and by doors in the tunnel, the air is forced through the drifts and out by the way of the avenue. The workings have not yet crossed the channel, and nothing is known positively in regard to its width. The company have at present all the men they need, or will need for a long time, and it is useless for miners from abroad to apply for work at present, as it is the policy of the company to employ men resident in Sierra county in preference to outsiders. We notice that the company has a series of rules posted at the tunnel mouth. Among others is one to the effect that men getting intoxicated and failing to report for work at the proper time, may consider themselves discharged. Water to wash gravel will probably hold out for six weeks or two months longer, after which pumping will have to be resorted to or washing stopped.

Trinity.
ANOTHER RICH LEDGE.—*Trinity Journal*, June 2: Mr. J. W. Blakemore was in town last week and

left with us a specimen from a rich quartz ledge recently discovered by Uncle Jimmy Blakemore, and which lies just over the ridge from Eastman Gulch and on the Jennings Gulch side, being about one mile southwest of the rich ledge owned by Mr. C. Hickey. This is the eighth gold-bearing ledge which has been discovered by "Uncle Jim", but far exceeds in richness any that he has before found. The late discovery is well-defined and is from 18 to 24 inches in width, the rock being estimated to go from \$100 to \$300 to the ton in free gold. Rock is now being taken out and crushed in an arrastra in Eastman Gulch and we hope to hear of large results when a clean-up is made.

NEVADA.

Washoe District.

HALL AND NORRIS.—The new winze now being sunk on the 2600 level is now down 15 ft, and at the bottom ore assaying from \$20 to \$30 per ton. It is supposed that this is from a new streak, as it is not thought that the winze is deep enough to cut the Keating vein, which lies to the westward a few feet. Two or three new streaks of ore have been found to the west of the Keating vein in cutting out and enlarging the station. Night before last, at a point where they are enlarging for a car-track, they found a feeder some five inches wide, which shows fine ore. There are still feeders of ore coming in where work was discontinued at the west wall of the station, and the ground in that direction presents a very favorable appearance. Everything seems to indicate that they are on the top of what will prove to be a favorable deposit of ore. They have drifted on under the winze that starts on the 2400 level, and have opened a chamber for an upraise, but the upraise itself has not been started, as they are awaiting the co-operation of the Chollar folks in this work. Only about 80 ft remain to be excavated to make this connection. It will be of immense value as it will give thorough natural ventilation to a large amount of ground which is now very hot. The ore brought up out of the new streaks yesterday shows well in sulphurets and chlorides.

SIERRA NEVADA.—On the 2900 level the joint Union Con. winze is down about 88 ft, and is in a favorable formation of vein material.

BEE AND BELCHER.—The northwest drift on the 2500 level is advanced in ground that is hard and dry. The diamond drill shows that this character of ground will continue for a considerable distance. It has been long since there has been any crosscutting in this mine. They will soon be in a position to make extensive explorations.

YELLOW JACKET.—This mine is yielding well at nearly all points. Quite a bonanza of low-grade ore has been found in new ground on what the miners term the "Frog Pond Level." This is really quite a valuable discovery.

OPHIR.—A considerable quantity of ore is still being extracted from the croppings, and this work will be much facilitated by the opening out of the old tunnel.

POTOMAC.—Although active prospecting is not in progress in this mine at present, the developments in the adjoining mines show that they have a valuable streak of ground to the west.

CON. VIRGINIA.—On the 2700 level the drain is completed. The west drift on the 2700 level is making good progress in very favorable vein material.

Rebel Creek District.

THE OHIO MINE.—*Silver State*, June 1: Joseph McColley, one of the owners of the Ohio mine in Rebel Creek district, informs us that work is being prosecuted steadily on the mine, which continues to look remarkably well and produce rich ore. Some 12 or 15 tons of the ore will be brought here shortly for shipment.

Bullion District.

RICH ORE.—*Fresno Times-Review*, June 1: It is reported that large bodies of rich ore have been found in Bullion district, south of Beowawe, and across the mountain from Lewis.

Columbus District.

BROKE THE MAIN SHAFT.—*True Fissure*, June 2: The main shaft in mill No. 1, or upper mill, of the Northern Belle company, at Belleville, broke on Thursday night. This will necessitate the complete closing down of all the machinery in the mill until a new shaft can be received from San Francisco. The steam cylinder of the engine has needed repairs for sometime, and will be attended to during the two weeks' stoppage.

PUSHING THE WORK.—The new site of Columbus Con. hoisting works is one of activity. A large force of carpenters, masons and laborers are busy framing the building, putting in the engine and other foundations, and clearing the ground in the vicinity of the new shaft, which has already been sunk a distance of 60 ft. The new works will be the largest in the district, and will be ready in about three or four weeks. A description of the building and machinery will be given next week.

MOUNT DIABLO.—The stope from the lower winze No. 2 shows two feet of \$70 ore, and the stope above the third level, near the head of this winze has developed some 15 inches of \$85 quartz. The stope above the west drift from the Callison winze is looking well, the ledge averages fully two feet in width, the grade of the ore being about \$75 per ton. A small amount of ore of a good grade continues to be extracted from the first level and from the Mount Diablo adit. A shipment of bullion amounting to \$5,125.59 was made May 24th, and another of \$3,494.53 on the 28th ultimo.

Grantsville District.

QUIET.—*Grantsville Bonanza*, June 2: Everything is as silent as the tomb in the Alexander and Brooklyn mines. Active operations have not yet been commenced.

Lewis District.

RESUMING OPERATIONS.—*Fresno Times-Review*, June 2: Work is to be resumed on the Dahlgren mine, at Lewis. T. G. Morgan, Supt. of the mine, has returned from Arizona, where he had been examining mines for Eastern parties, and he goes direct to Lewis to make arrangements to commence work.

Mount Cory District.

REDUCTION WORKS.—*Bodie Free Press*, June 2: Warren Loose returned Friday from a trip to Mount Cory. He says that the Mount Cory Co. have graded out a place 100x300 ft for their reduction works, and that the contract for erecting them has

been awarded to Salkeld & Eckert. This is four miles from Hawthorne and several miles from Coryville. Money is scarce in the new camp, but hope is high.

Ophir Canyon District.

BULLION.—*Grantsville Bonanza*, June 2: The Twin R. M. Co., Ophir canyon, is shipping bullion steadily. It looks as if Ophir is on a fair way to become a flourishing camp once more.

Taylor District.

NO WORK.—*White Pine News*, June 2: Parties in from Taylor District inform us that there are close on to 300 men there—only about 40 of whom are working. Every large-sized sagebrush in the vicinity has a camp beneath it. Taylor is expected to boom this summer, but just now is no place to go hunting work.

Union District.

NOT PROSPECTED.—*Grantsville Bonanza*, June 2: Union mining district has never been prospected to any great extent and the discovery of new mines as valuable as any yet opened will not surprise any one acquainted with the district. James Liston, Jake Gooding, Steve Merton and W. Crowell are working their mine in Union district with the most encouraging results and they are taking out some very high grade ore.

Washington District.

REDUCTION WORKS.—*Grantsville Bonanza*, June 2: Reduction works will probably be erected for the purpose of converting ore from the Hon. A. J. Franklin's mines into bullion.

ARIZONA.

A REVIEW.—*Tombstone Epitaph*, June 2: In the varied experiences we have had of mining camps on the Pacific coast we can not call to mind one instance in which so various a display of ore can be shown up, or so general a mineral impregnated region exposed, as in the Tombstone mining district. In new mining regions developments are few and far between, but here week by week we have to record not only the development of ore bodies already known, but the existence of new leads, which so far have never been heard of in public, and in places that no mortal man would look for mineral bodies of ore, are found by hard work and indomitable courage. The inference, therefore, is, that as a mineral region Tombstone is unsurpassed in any State or Territory of the United States of America, and that as our mines are only in their infancy we have before us a future and such a future as none of those resident here can or will be ashamed of. Since our last report we can record new developments in the Alps, Ground Hog and Prompter, tending to confirm our statements; and from the appearance of each and all they are permanent developments, and as such will do much to keep the character of Cochise county mines before the eyes and recollection of capitalists. Within the next year, we predict not only a boom here, but the permanent investment of capital that will do us all good, and make the name of Tombstone (ludicrous though it is) at least as great historic fame as has ever been gained by the Comstock or Virginia City in its palmy days.

COLORADO.

A STRIKE IN LINCOLN TUNNEL.—*Georgetown Courier*, May 31: Dumont was somewhat excited Saturday, by a good vein of ore having been encountered in the Lincoln tunnel property of the Albion G. & S. M. Co., of Philadelphia. The long looked-for and anxiously expected California lode has been intersected. The vein exposed so far shows eight inches of solid ore, carrying yellow and gray copper. This mineral has all the characteristics of that found in the Albion mine. The facilities for extracting the ore cannot be excelled in the county. The crosscut tunnel, situated as it is near the base of the mountain obviates the necessity of a wagon road being built, as a chute is the most feasible. This tunnel is unquestionably the main avenue to all the properties located upon Albion mountain. The owners deserve all the profit that can be derived from what appears to be so splendid a bonanza. There untiring patience, perseverance and confidence is worthy the emulation of other companies in this vicinity. The Mansfield company should take this into consideration.

IDAHO.

ORE AND BULLION SHIPMENTS.—*Wood River Times*, May 26: Ore is rolling down from the Davitt, Jay Gould, Idaho Democrat and other mines to the sampling works here, thence to the Ketchum smelter, and back in base bullion bars for shipment to Omaha by rail. The shipments are becoming larger each week, and soon the bullion shipments will be the best evidence of the mineral resources of this section.

THE WARM SPRINGS DISTRICT.—The mines in the Warm Springs district are all showing well in depth. The mines are now down 50 ft, with a vertical shaft on the Island mine, in quartz and galena. The vertical shaft on the Night Hawk is sunk to the depth of 75 ft, with a well-defined vein and a 14-inch body of shipping ore at the bottom. The main shaft on the Black Hawk mine is down 280 ft, and each shift is sending up tubs full of galena which will sell at good figures on silver assay. There are 1,400 to 1,500 tons of ore out on the dump at the Irvine mine ready to be hauled to the Ketchum smelters, and more piling up daily. The Irvine and West Fork groups of mines are so productive at present that the Philadelphia Co. counts upon a sufficient supply from them to keep the smelting works running, and the manager expects that they will ship 6,000 tons, the present season. The East and West Forks, Elkhorn, Greenhorn, Trail, Eagle, Lake and Boulder creeks, with North Fork thrown in, are clear of snow on the south hillsides, and ready for mining operations. Numbers of men are camped at their respective claims, starting work for the season.

THE NEW SAMPLING WORKS.—*Wood River Times*, June 2: The new Hailey Sampling Works will be under the personal supervision of Mr. Moulton, one of the proprietors, who will endeavor to see justice done to both buyer and seller. The foreman will be W. W. Phillips, one of the best samplers on the west side of the Rocky mountains, who comes here from the Utah Sampling Mill, Salt Lake, where he has had several years' experience; and the book-

keeper will be C. P. Tatro, who resigned the Postmastership of Bellevue to take charge of the books. In addition to the above staff, some 25 to 40 men will be employed.

MONTANA.

BUTTE MINES.—*Inter-Mountain*, May 26: On the 200-ft east drift of the Magna Carta a south crosscut lately extended to intersect the south vein, has opened two ft of ore which yesterday sampled \$75.77. The Paser shows up a magnificent ore body in the crosscut from the bottom of the east shaft. For a solid width of 18 ft the ore samples 35 ounces, but an eight ft breast is being extracted which assays between 40 and 75 ounces. O'Donnel brothers who have a lease and a \$50,000 bond on the Sun Burg are making arrangements to erect a steam hoist on the property. In the Mice, on the 100 and 200 ft south levels, the extraction of about 20 tons of ore daily, continues. The 300-ft north crosscut of the Bell has been started from the new three-compartment shaft but the work does not interfere with the sinking which will be continued to the 400-ft station. The Lexington mine and mill are running smoothly and the production of \$50 and \$60 ore remains at about 60 tons daily. The output this month promises to exceed \$95,000. The Colusa is producing between 75 to 100 tons of ore daily, according to the requirements of the smelter. The Moulton keeps on the even tenor of its way and under the charge of Mr. Pat Clark, one of the best practical miners in Montana, is making a very satisfactory record. The upper levels of the mine show an abundance of ore which is so accessible that the working force has been considerably reduced and the output is still in excess of the capacity of the mill.

NEW MEXICO.

COAL CROPPINGS.—*Las Vegas Gazette*, May 22: At last it seems to be an established fact that Las Vegas is to be supplied with coal from its own vicinity. Much excitement was caused yesterday by the news that a fine three-foot vein of true carbon had been discovered by some workmen engaged in excavating for a culvert on the bank of the Gallinas just in the rear of the Montezuma hotel at the hot springs. The coal, which lies near the surface in a locality where it can easily be worked, is pronounced by experts to be of a very superior quality—and while the extent of the deposit cannot be estimated as yet, it is reasonable to suppose from the formation, that the supply will be immense. Another fine cropping of very superior coal has been discovered by a miner named Howard, at Mineral Hill, 15 miles from this city. A couple of sacks of the product have been brought into town and are now on exhibition at N. L. Rosenthal's store. Howard will put on men to develop this showing at once, in order to claim the bonus of \$500 offered by the board of trade to the first person who shall produce a good mine of the precious fuel within reasonable hauling distance of Las Vegas.

VICTORIA MINING CAMP.—*Southwest Sentinel*, May 26: This camp is a very promising one. It is situated in the southern portion of Grant county, about three and one-half miles south of the S. P. railroad, and in a direct line from Gage station. But very little has been said about this district, for the reason that very heavy capitalists are interested, and as they do not desire to sell but anxious to buy more, it is not to be expected that much information can be gleaned from them. However, having been on the ground ourselves we know something about the camp. Messrs. Hearst & Head own five claims in the district and have about 30 men at work on the Last Chance mine. This is an excellent piece of property and is so regarded by the owners, who understand mining operations as well as anyone in New Mexico. The formation is limestone and the ore is found in "pockets" or chambers. Often some very large bodies are found in some of the ore deposits. They are down 250 ft with their deepest shaft and have extracted a great quantity of mineral. It runs on an average 32 ounces in silver, \$12 in gold and 35 lead. The camp contains about 30 men. The But Cut is another good claim. Mr. Callahan, who is the superintendent and represents a N. Y. Co., has 400 ft of work done on it, and is opening it up rapidly. He and Hearst & Head are shipping their ores to Benson, A. T., where there are good smelting works. They ship on an average 150 tons per day, and are realizing handsome profits in the transaction. George E. Price has nine claims in this camp, all of which are looking well. The Jefferson mine, owned by Charles Fuller and John Grondhouse is an excellent piece of property. The owners have now on the dump about 100 tons of heavy lead ore. The Arizona, owned by a St. Louis Co., is looking splendid.

FLEMING DISTRICT STRIKE.—*Las Vegas Gazette*, June 2: Native silver was struck in Old Man mine, Camp Penrose, the other day, and 30 tons of high-grade ore has been shipped. The real wealth of the new camp is only beginning to be known. Great excitement prevails over the late strikes, and everything is at high pressure. Capitalists are arriving daily, seeking investments in the new bonanzas. Property is changing hands at enormous figures, and the prospects are almost certain for still further advance. Thousands of people are flocking into the new camp, many hotels and stores are going up, and everything is booming.

UTAH.

A BIG MINING STRIKE.—*Salt Lake Tribune*, June 2: There was a rumor in this city last week of a big strike in Big Cottonwood, but it could not be traced to authentic source, and but little was said about it till yesterday, when parties who visited the mine confirmed the previous report. The strike was in the property of the Silver Mountain M. Co., which is situated on Kessler's Peak, Big Cottonwood. For some time past a tunnel has been run to cut the vein, and this was accomplished last week when the tunnel had penetrated the mountain 400 ft. An ore body five ft wide, the first-class assaying 55 ounces silver, 58 lead, 33 gold, the second class 23 1/2 ounces silver, 26 lead, was encountered. The tunnel is 400 ft below the upper workings, and all the ore can be extracted through it. The strike is the most extensive that has occurred in Big Cottonwood in several years, and will do much toward causing others to develop their properties. Ore shipments will begin as soon as the roads are put in condition, and Silver Mountain will add its wealth to the prosperous Territory.

The Cedar of the Gods.

[Written by Mrs. JEANNE C. CARR.]

An unexpected but most welcome rain has left all our young conifers in their Sunday's best, and so beautiful are they that I would fain add my weak voice to the chorons of rejoicing and praise outpoured by a thousand feathered songsters this May morning.

Of many delightful trees the accompanying faithful portrait will give a very correct idea of the typical form of the Himalayan or Indian cedar in youth. Our specimen, fifteen feet high, was purchased of W. B. West, of Stockton, in 1878, and brought here in a four inch crotch, with a small specimen of the Cedar of Lebanon, both in my lunch basket.

Each are now developing their distinct characters, and looking upon the exquisite drooping grace of the one, and the sturdy horizontal arms of the other, I send my thoughts afar to the scenes where these noble representatives of forest grandeur are native.

The Deodar forms vast forests in the Himalaya mountains, where the eminent botanist Sir Joseph Hooker studied it, and recorded his observations in the "Himalayan Journals" more than twenty years ago. The brothers Schlagintweit were among the earliest botanists of these elevated regions, and I shall never forget meeting one of them at an inn in Mariposa, in the summer of 1869, he returning from, and I going to worship in the Big Tree Groves. His comparison of the Asiatic and American Cordilleras was most interesting and instructive. The people who live in the chalets among Deodar are brave and patriotic like the Swiss; and passionately attached to their mountain homes. They are often fair haired, and of a lighter complexion than the inhabitants of the plains. In times of which chronology has no measure, the ancestors of these hill people worshipped trees, and built vast temples in the plains below; it does not appear that the Buddhists now specially reverence any vegetable except the banyan.

The uses of the Deodar are manifold; it serves every purpose of our large family of firs and pines.

Remembering that the Deodar on its native heath enjoys a rainfall of 120 inches, I am surprised to see how well it has accommodated itself to a climate with less than twelve inches. The next ten years will be of much more importance in demonstrating whether these trees can be truly acclimated here, than the past five have been, for we tend our young conifers like so many babies. Shading them when necessary, and mulching them abundantly. All the shavings from our new house have been carefully saved for this purpose.

In close proximity with the Deodar stands my Cedar of Lebanon, very different in color, this being a rich grass-green, while the Deodar is silvery; should they live fifty years, their heads will touch each other. And this tree, too, was studied by the botanists just mentioned, not only on Lebanon, where a few specimens remain of the great forest which Hiram, King of Tyre, cut down to oblige King Solomon, but also in the Taurus mountains, where there are virginal forests still preserved, because there is yet no means of transporting the precious timber when it may serve the builder's uses. The oldest specimen of the Cedar of Lebanon in Europe is in the Jardin de Plantes, in Paris, where it was planted by De Candolle, who brought it from Palestine more than a century ago. It is related that the vessel in which he crossed the Mediterranean was unseaworthy, and in the prolonged voyage the sailors and passengers suffered greatly for water, but De Candolle resolutely denied himself, and gave his scanty portion to the little tree, which, thus saved from perishing, has become his monument. The oldest Cedar of Lebanon in the United States is in the Bactran Gardens, in Philadelphia. This was raised from a seed.

During his visit to this coast in 1879, I was surprised to hear Dr. Hooker say that he considered the Cedar of Lebanon and the Deodar specifically identical, the change of habitat accounting for the difference in their appearance and mode of growth. I rather resisted this view, having had no opportunity to compare the cones, but the better I become acquainted with them, the more I become of his opinion. Then the way that our Pacific coast conifers are behaving under cultivation in England, unsettles ones cherished ideas about permanence of characteristics. Now, *Thuja gigantea* is here a massive tree of compact form, usually a dense pyramid of living green; but a variety sold in England as *Thuja Lobbi* is described as looking like "a delicate fishing rod laden with the most exquisite fronds of ferns, each standing quite clear of its fellows, by reason of the rapid growth of the central shoot."

The above description is not too florid for our beautiful Deodar. And right here let me say a word about pruning these trees. I was inexpressibly shocked last October, on a brief visit to Sacramento, to find the pride of the Capital park, John Ellis' splendid row of Deodars, hopelessly maimed and skeletonized by the shears. Ten years' growth can hardly repair the damage to their beauty. If let alone severely for that length of time, the side branches will grow out, droop downward and hide the disgrace of their naked trunks.

It is permissible to touch the Deodar with a knife when a riotous growth causes it to send up two or more leaders. Even then it is better

to wind a scrap of fine wire around all except the finest and strongest, thus forcing the sap to it; after a few weeks the ligatured branches will fall off, leaving no scar. And if it is ever necessary to prune the side branches, the cut should be made at least half an inch from the stem, and the cut painted or smeared with clay. The stub will recloth itself, and prevent diseases of the bark from exposure to sun and wind.

Deodars may be grown successfully from cuttings; they never make quite as handsome trees, but will serve an excellent purpose as screens. And there is no reason why a single Deodar should not adorn a town lot, for half a dozen years, even if want of space should require its removal afterwards. Very small conifers, weeping cypresses (not Monterey), and golden arbutus can be used with good effect in miniature grounds. The common American hemlock which grows slowly in California is one of the best for this purpose.

But I have wandered too far from my subject and purpose, which was to promote the culture of these lovely trees. In another paper I will gossip concerning the Anricaria family. Pasadena, May 6, 1883.

QUICKSILVER DISSOLVES GOLD.—Thos. K. Beecher, while investigating the mines at this place, decided a question which has long perplexed the practical miner—that is, that quicksilver will dissolve gold. Miners have always understood that nothing but "*agua regia*" would dissolve gold, yet they have known that mercury, after being used in saving gold, retained

THE DEODAR OF THE HIMALAYAS. (*Cedrus deodara*.)

a portion that was impossible to separate but by retorting. They called quicksilver in this condition "charged," but supposed the gold was merely held in suspension. Mr. Beecher, being a thorough chemist, described the test he had made, which left no doubt that mercury will dissolve gold to the extent that miners understand by the term "charged." This fact being understood, it is evident that mercury used in a flume, though the "clean-up" may be small, yet the mercury will contain, in solution, as much gold as if it had amalgamated a greater amount of gold. Therefore, miners should retort their quicksilver after every "clean-up" to save the loss of the gold which necessarily wastes with the waste of quicksilver, that this scientific discovery places beyond a peradventure.—*Placer Times*.

In the middle ages, the production and use of copper would seem to have been, in a great measure, abandoned, probably because of the discovery of the more precious metals with which it was found associated. At least the records of that period in the world's history contains little concerning the working or use of the metal.

In the year 1844, the Lake Superior copper mines were discovered, and these have since proved to be the richest and most productive mines of copper in the world. Abundant evidence of the previous working of these mines were found in the rude stone tools and primitive appliances for reducing the ore which had been left by an unknown people, who had, in ages past, inhabited this continent, and whose history is unwritten.

Wood River.

Many new comers express surprise that there is not a greater number of people in town, and that the streets are not crowded with men. Of course citizens of Hailey feel a natural interest in seeing strangers favorably impressed with this section upon their arrival; but such observations as, "The town looks quiet, and few people are to be seen," evince a superficial perception on the part of those who express them.

Last year there were computed to be 10,000 miners, prospectors and residents of all callings in the Wood River country. Of that number the towns contained not over 3,000. This season so far, with the arrivals in Wood River averaging 40 daily, the towns are not increasing much in population, and this fact is the best evidence that the country is growing as it should—for permanence. Out of 1,000 arrivals this spring in Hailey, not 200 have remained in town. Every day—especially early in the morning—parties on horseback leading pack animals loaded with tools and mine supplies may be seen starting out in every direction for the hills, to prospect or work mines already located. Not less than 100 men have gone from town the present week, and every man who leaves for the mines becomes a producer of wealth, and each town eventually receives a proportion of the product of his labor.

The present season there will be 20,000 miners and prospectors in the Wood River country, while probably the population of the towns will not be increased more than half. To any prac-

Snake River Placers.

A New Method for Working the Fine Gold.

It really looks as though the method of saving the fine gold in Snake River valley has been found. The credit is due to a company of working miners, men who have followed mining all their lives. The idea seems to have been borrowed—at least in part, from the manner in which tin is saved in Cornwall. The best of it is that no ponderous and expensive machinery is required. The method is simplicity itself, and any jack-carpenter can make a machine in a couple of days. A machine requires one man to run it, and from the first 40 hours' run \$89.50 in gold was retorted.

It is not claimed that all the gold was saved, but it is unquestionably true that more is saved than by any other method hitherto tried. These men bought twelve planks in Ogden, paid \$1 a plank freight to get them to Eagle Rock over the Utah & Northern, and in a few days went to taking out gold. Some rough lumber they bought here, but there is not probably exceeding 300 feet in the entire machine. It is no longer a question of faith, and this company of miners have already commenced to multiply their machines, with the same certainty of being engaged in a legitimate business that will pay them from \$7 to \$10 per day to the man, that a farm hand in Missouri has when he works for \$15 a month.

And now, to give our readers some crude idea of how the gold is saved. A sluice box with a false bottom is constructed; the false bottom is of perforated sheet-iron. The gold and black sand drops through these holes on to the second bottom, while the coarser stuff is carried out and dumped into the river. Some twenty feet from the river, the sand and gold drop through a slit in the main sluice into a second sluice box, just under and crossing it at right angles, or like the top of a letter T. This last box has a number of smaller sluice boxes, reaching from it toward the river, and casting the water and lighter sand into it. The whole is something in the shape of a stable fork, the handle being the main box, the cross-piece being the second or lower sluice box, and the tenth representing the final boxes, after passing through which the water is allowed to waste. The bottoms of these last boxes are padded with burlap, which is removable at pleasure. In the burlap is where the gold is found, and about once in every twenty-four hours the burlaps are wrung out into a tub and the gold is retorted. There are some devices adding to the perfection of the machine which are not necessary to mention, as an effort so to do would result in confusing the reader. It is enough to know that each machine is good to save, say \$20 a day, and that two men are sufficient to run it twenty-four hours—or one man on duty at a time.

Water, of course, is a side question—but there is plenty of water. In high water Snake river can be brought into use. There we have North Willow creek, South Willow creek and Sand creek. When all these get low, the Snake River Water Co. can supply any amount of water through their canal and put it anywhere.

It is hard to say what the result of saving this gold is to be. There are a million acres of land, and you can find the color anywhere. D. F. Chamberlain showed me a pan he had just washed out below town, and there were a thousand colors in it. Only yesterday the writer picked up a pebble fully a mile from the river on an open prairie, and few gold colors discernible in it to the naked eye. If that pebble had remained, in a few hundred years it would have dissolved and added its little specks to the other specks that have been released from similar stones, and one more color would have been found by the man who shall wash a pan of dirt from that spot a thousand years hence.—*Cor. Salt Lake Tribune*.

Leaching Works.

It will be remembered that some time ago Albert Arentz visited Eureka, bringing with him 15 tons of ore from the Mt. Cory mine, near Hawthorne, to test the reduction of it in the Geddes & Bertrand mill by the leaching process. He went away delighted with the working of this plan and reported the same to the Mt. Cory Company, who accepted his suggestion to adopt the leaching process for their ores, and have appointed him to superintend extensive new works about to be constructed at Coryville. These works are thus described by the Walker Lake *Bulletin*: The main building will be 300x140 feet, and the entire works when completed will cost about \$150,000. They will doubtless be the best on the coast, as every useful improvement in machinery and process will be adopted. The works will consist of a mill and improved Brockner furnace, capable of working from 60 to 70 tons daily. It is not to be a stamp mill, but a leaching mill with revolving furnaces. Krom rolls, somewhat similar to Cornish rolls in appearance, but of greatly improved construction and manner of working will be used. The ore will first be broken in rock breakers, from which it will pass to an improved form of dryer. After drying it will be put through the rolls, where it can be crushed to any fineness required. After crushing the pulp will be put through the chlorinizing furnaces, of which there are four, and from the furnaces will be taken to the leaching vats, which are operated by an improved method. The silver is precipitated in the vats and is then melted into bars.—*Eureka Sentinel*.

MINERS—and by this term we mean men who own mines and work them—are not at all pleased with the law which allows a man to locate any number of claims and hold them by trickery. One operative miner yesterday told us that in his immediate neighborhood a certain man claims, for himself and others, perhaps forty claims, some of which are good and would be worked if they could only be located by working miners. The claim-owner in question holds his ground as long as the law will let him. His plan is, not to do assessment work, but to watch and wait until time is up, when he relocates and holds them for another period. This kind of performance should not be encouraged. Mines can never be developed in this way, so that it is not strange that working miners desire a change in the law.—*Prescott Courier*.

A Bright Outlook at Safford District.

Never in the history of Safford district did its mines look better than they do to-day. News lately received from that section pictures the scene as bright and encouraging. The Onondaga, the mammoth mine of the camp, under the able management of Col. Tyson, has been stripped on the surface along the ledge a distance of 800 feet, exposing ore varying in width from eight inches to six feet, and in price from \$30 to \$450 per ton. A force of 20 men is employed at present, and more are to be put on as soon as necessary tools arrive from Salt Lake City. A new tunnel has been started about 25 feet below the old workings, which is to be run a distance of 800 feet, there to connect with a shaft which is being sunk on ore on the northern end of the claim. The outlook on the surface is more than encouraging, and should the ore continue down, the wealth of this mine would be fabulous. Fully 800 sacks of ore are awaiting shipment to Salt Lake, and a large quantity is lying loose on the various dumps preparatory to sorting and sacking.

The Zanolli

This claim is really at present the only well developed one in the district, and shows a considerable amount of work. The ledge was first encountered in the shaft at a depth of 30 feet, and has since continued down a distance of 112 feet, varying in width from three inches to six feet, the latter being the present width of the ledge at the bottom of the shaft. The ledge is perfect and well defined, the foot and hanging walls being plainly discernible throughout the entire depth of the shaft. The ore averages high, assays ranging from \$26 to \$300 per ton. Fully 125 tons are already on the dump, and a careful estimate of the ore in sight in the mine, places the value at \$40,000. The owners of this property deserve encouragement, as they persistently toiled and labored in pushing a tunnel a distance of 300 feet without success, finally going to a place above, where, at a depth of 300 feet, the ledge was encountered. If present indications continue, it is the intention of the owners to erect a mill on the Humboldt river, at Girard, about a mile distant, where it is estimated ores averaging \$12 per ton can be worked at profit.

The Other Mines

In the district we pass for the present, as sufficient developments have not been made to ascertain the extent of the ledges. Assessment work is being done on most of them, and it is calculated that by the 1st of June, fully 100 men will be at work in the district. The country abounds in ledges, and the appearance of the Onondaga and Zanolli should encourage owners in the vicinity to commence operations immediately upon their properties.

The Country

Is all that could be desired. Wood and water are abundant, Safford canyon being a net-work of springs and water courses. The Humboldt river is distant but a mile and a half from the mines, where ample water power can be procured for mill purposes. A little settlement has been established at Gerald station, where the C. P. trains stop for passengers coming and going to the mines. At Safford a number of comfortable dwellings have been erected, where hereafter man and beast may be accommodated. Several buildings are shortly to be removed thither from Palisade, and the 1st of July will see a thriving little village in the northern end of the county.

"The Sleeping Village,"

As Palisade has been termed by some, will receive untold benefits should the future of Safford prove as now anticipated. Commerce and travel must necessarily center at that place, and already the little town is beginning to feel the effect of operations at Safford. Baum, the genial proprietor of the Depot hotel, is renovating and otherwise improving its popular hostelry, preparatory to the anticipated rush. The Palisade hotel has fallen into the hands of D. T. Jones and wife, a deserving couple, and is being conducted in a first-class manner, and though it is situated a little out of the line of travel, they will undoubtedly get their share of patronage. Syl. Bunta, an old Tuscaroran, has leased the Hogle corner, and is apparently doing a good business. Tom Jewell, S. S. Carney, "Curley" and all other old standbys are still wrestling with Dame Fortune, and appear to be perfectly contented in placidly waiting the coming boom. The E. & P. Railroad shops are in full blast, the climate is lovely, the people are happy over the bright prospects, and it is more than probable that ere many months roll around another promising camp will be added to the taxable property of Eureka county.—*Eureka Sentinel*.

NEXT to iron, copper is the most useful metal in the world. In its general distribution, it comes next to that most important of all metals. The qualities of durability, malleability; ductility, etc., it possesses render it adapted to a great variety of purposes.

THE general work at Tombstone progresses steadily and energetically. Those mines which have not reached water level are doing their utmost to reach that point, as it is a foregone conclusion that the developments beneath this level are likely to be productive of better ore than what has been found above.

USEFUL INFORMATION.

The Manufacture of Watches.

Few persons estimate the amount of work in a watch of modern manufacture. Nearly a thousand processes are used in completing them. There are fifteen distinctly different kinds, and as many as 150 varieties of finish, number of jewels, construction of balances, etc., independent of cases and their varieties. Women are largely employed in the work of watch-making, especially in Switzerland. But since the year 1850, the whole process has undergone immense change by the substitution of machinery for hand work, which originated with Mr. Dennison and Edward Howard, of Boston, who established the first manufactory of watches at Roxbury, Mass., when it was moved, in 1854, to Waltham, on the Charles river. Each separate portion of the watch is made on a machine specially constructed for the purpose, and the gauges employed are so accurate that 1-1700 part of an inch can be measured. Some of the portions used in watch making are so minute that it takes 150,000 of them to weigh a pound.

WATER GLASS IN PAINT. Water glass is now being made use of in the production of a paint which, in addition to its beauty and durability, is also advantageous as a means of protection against the action of fire. As a floor paint it is found especially valuable. The surface having been well cleaned, any crevice, or cracks between the boards are next luted with a thick mixture of water glass and pulverized chalk or gypsum, then, by means of a stiff brush, a coating of water glass, of syrup-like consistency, is spread over the floor, and to this succeeds a second coating of the same, mixed with a desired color—the latter a mineral color, as the alkalis of the water glass commonly decompose vegetable colors. This coating having become dry, other layers of the water glass are given, until the floor acquires a fine lustrous appearance. In order to insure a polished brightness, the surface is ground off a little, oiled, and thoroughly dried. The water glass is not worn away either by heat or by continued use.

MELTING IRON WITH COPPER.—In the new alloy of copper, iron and zinc, considerable difficulty has been experienced in securing a uniform admixture of the iron. A London experimenter is said to have overcome this by his method of introducing the iron into the mixture of zinc and copper. When ordinary wrought iron is introduced into molten zinc, the latter readily dissolves or absorbs the former. The exact point of saturation, or the proportion dissolved or absorbed, varies with the temperature at which the molten zinc is maintained during the process, and it is by carefully ascertaining and controlling this temperature that a perfectly uniform product has been obtained. The metal thus produced, and to which the name of delta metal has been given, is stated to be as much superior to brass as phosphor-bronze is to gun metal, or as steel is to iron. It possesses great strength and toughness, and samples cast in sand give a breaking strain of twenty-two tons per square inch.

FENCE POSTS THAT WILL LAST.—A writer in an exchange says: "I discovered many years ago that wood could be made to last longer than iron in the ground, but thought the process so simple that it was not well to make a stir about it. I would as soon have poplar, basswood, or ash as any other kind of timber for fence posts. I have taken out basswood posts after having been set seven years that were as sound when taken out as when first put in the ground. Time and weather seemed to have no effect on them. The posts can be prepared for less than two cents apiece. This is the recipe: Take boiled linseed oil and stir in pulverized coal to the consistency of paint. Put a coat of this over the timber, and there is not a man that will live to see it rot."

A NEW INVISIBLE INK.—C. Widemann communicates a new method of making an invisible ink to *Die Natur*. To make the writing or the drawing appear which has been made upon paper with the ink, it is sufficient to dip it into water. On drying, the traces disappear again, and reappear by each succeeding immersion. The ink is made by intimately mixing linseed oil, one part; water of ammonia, twenty parts; water, 100 parts. The mixture must be agitated each time before the pen is dipped into it, as a little oil may separate and float on top, which would leave an oily stain upon the paper.

HEMLOCK TIMBER.—The timber of the hemlock tree is rejected by the builders, and yet it might have its important uses. "The stone which the builders rejected, the same became the head of the corner," seems to apply to hemlock for granaries. It is claimed for it that it will keep rats out, as they will not gnaw it in consequence of the sharp slivers penetrating their jaws, and they lose all relish for the grain beyond. This hint should be taken advantage of.

NEEDLES AND PINS.—One of the flourishing industries of Germany is that of the manufacture of needles and pins. The eight manufactories of Isenlohn alone consumed in 1882 no less than 600 tons of wire, employing 800 male and 700 female and juvenile work-people, besides seven steam engines and four water wheels of 230 horse power. A large export trade is thus maintained.

FRONIZING.—How to make woods, such as cherry, mahogany, etc., look like ebony, is often desirable, and a correspondent of the *Hub* gives the following directions: To imitate black ebony, first wet the wood with a solution of logwood and coppers, boiled together and laid on hot. For this purpose two ounces of logwood chips, with one and a half ounces of coppers, to a quart of water, will be required. When the work has become dry, wet the surface again with a mixture of vinegar and steel filings. This mixture may be made by dissolving two ounces of steel filings in half a pint of vinegar. When the work has become dry again, sandpaper down until quite smooth; then oil and fill with powder drop black mixed in the filler. Work to be chromized should be smooth and free from holes etc. The work may receive a light coat of quick-drying varnish, and then be rubbed with finely pulverized pumice stone and linseed oil until very smooth.

LUMINOUS PAINT IN RAILWAY CARRIAGES.—Luminous paint appears to be steadily working its way into practical use. A railway carriage painted inside with the Balmalm phosphorescent paint is included in one of the trains between London and Rotherhithe via the Thames tunnel. Although only one-half of the available space of the carriage is painted, the phosphorescent light is quite sufficient to enable the passengers to distinguish small objects when passing through the tunnel; and, moreover, the light is powerful enough to enable the indication of an ordinary watch. It is probable that the railway companies will be enabled to effect a considerable saving of gas and oil by using the phosphorescent paint.

TO CLEAN A WATCH.—Place a watch, with the case open and the works in motion, in a vessel so that the watch will be entirely covered with benzine. After three hours it will be found that the watch has been thoroughly cleaned. The vessel should be covered with parchment paper, and the watch, before it is removed, should be slightly agitated. Lastly, the watch is laid in benzine again, but this time a little petroleum oil is added, in order to lubricate the machinery.

TO POLISH STEEL.—Mix half a pound of fine emery powder with the same quantity of soft soap, and add a small piece of soda. Simmer this over a slow fire for two hours, to extract all the moisture. Rub on with a flannel, and finish with plenty of dry whiting.

GOOD HEALTH.

Sleeplessness.

A physician, writing in the *Christian Union* on this subject, remarks:

The causes that produce this serious trouble are various. Not unfrequently the tendency to it is inherited with a delicate nervous organization, and overwork will increase it. It is difficult for the sufferer to know just how much work, mental and physical, may be accomplished without producing the unpleasant result. For one so constituted a most watchful care becomes important, and the most interesting employment must be turned away from at the first sense of weariness.

An earnest conversation with a friend exciting your sympathy, the demand upon your strength made by an invalid, reading an article that stimulates the mind to intense thinking, may, any of them, cause you to spend weary, wakeful hours and lead to severe exhaustion on the morrow.

By watchfulness you may learn to spare yourself the over-fatigue, as a duty which others may not understand the reason for. You may avoid the conversation and the book at evening, seeking them at an earlier hour when the choice lies with you. But with every care you are liable to suffer from causes you can neither foresee nor prevent.

Sometimes indigestion will awaken you at the small hours, and take revenge for some very slight departure from the careful diet you uniformly adopt. Recently it has been discovered that many persons lose hours of sleep because they are in need of nourishment; that the fast is too long that continues from supper time at six o'clock until six or eight o'clock the next morning.

Physicians who used to prescribe bromide of soda or potassium for sleeplessness now urge their patients to take beef-tea instead. The writer, after trying various prescriptions with little benefit, was at length so fortunate as to receive such advice. At first beef-tea was used with some light bread or biscuit broken in it, sipped from a spoon as warm as it could be taken. Afterwards milk, just scalded, not hoiled, was substituted, and to make it more easy of digestion, a teaspoonful of lime-water was added to half a tumbler full of milk. To facilitate matters, a pocket stove with an alcohol lamp, or an arrangement for the gas fixture, should be at hand. If neither beef-tea nor milk can be easily procured, hot water, with an infusion of hops or mint, may be substituted, or even hot water alone will quiet restlessness and induce sleep. A darkened room that the moonbeams cannot enter, a little fresh air from an open fireplace or window, are valuable assistants in making the sleep continuous.

When once the habit of wakefulness is broken up, the beef-tea or milk may be taken cold,

but not iced. If you are always a poor sleeper, it will be well to continue this late supper as a permanent thing in your daily life.

Provide for it in the case of aged and delicate persons who may be under your roof; and, as the troubles of life appear most weighty when scanned in the midnight hours, you may be able to lighten the load for the rest of their journey.

Practical Hints about Glasses.

Persons finding their eyes becoming dry and itching on reading, as well as those who find it necessary to place an object nearer than fourteen inches from their face to read, need spectacles.

Persons under forty years of age should not wear glasses until the accommodating power of the eye has been suspended and the exact state of refraction determined by a competent ophthalmic surgeon.

The spectacle glasses sold by peddlers and by jewelers generally, are hurtful to the eyes of those who read much, as the lenses are made of inferior sheet glass and are not systematically ground.

No matter how perfectly the lenses may be made, unless they are mounted in a suitable frame and properly placed before the eye, discomfort will arise from their prolonged use.

There are three systems of grading spectacle lenses: the English, the metric, and the Prussian. Those made to supply the demands of the trade in this country are carelessly made, and are poor imitations of either the English or metrical system. The metrical scale has no equivalent, is not graded by any uniform rule of dividing the inter-focal spaces, and is therefore unsuited to the exacting demands of science.

The near sighted eye is an unsound eye, and should be fully corrected with a glass, notwithstanding the fact it may need no aid for reading.

The proper time to begin wearing glasses is just as soon as the eyes tire on being subjected to prolonged use.—*Medical Herald*.

PNEUMONIA.—One reason why pneumonia is so fatal in the spring is doubtless that people are not aware that the danger of contracting it does not pass off with the period of winter minimum temperatures. On the contrary, as an eminent medical authority has shown, "the latter part of the winter and the spring (during February and until June) is the season of pneumonia," especially of the disease in its complicated forms, with continued fever. The very dry polar waves may sap the strength of the body and make it a prey to insidious pulmonary disease. But they would be powerless to do this without the aid of the intervening spells of mild, moist, vernal weather, during which the alimentation of the body is light and the heavy winter clothing exchanged for stylish spring garments. In this latitude, when April arrives it finds all delicate, anemic and hard working people with a minimum of vitality and disease-resisting powers. The true preventive measures against pneumonia and the prevailing diseases of this inclement season are, therefore, a rigid adherence to winter dress and a generous diet for the next three or four weeks, with as much rest and recreation as possible.—*New York Herald*.

WARM BED CLOTHING FOR CHILDREN.—It is fully as important that children should be warmly clad at night as during the day. Nor is it sufficient that the bed-clothing should be warm. Indeed, we are apt to err in using too many blankets rather than too few. Then the restless child kicks off the cover, and from a warm perspiration becomes chilled through, and a severe cold is the consequence. Delicate children should sleep in flannel, while for more robust constitutions Canton flannel in the lighter grades is heavy enough. Night-drawers are to be preferred to night-gowns, and the legs of the drawers should be long enough to reach the feet. Indeed, the style which covers the foot also, like a stocking, is an excellent one for children who are restless sleepers. Night-gowns for babies should be long enough to come down well over the feet, and flannels should be worn in cold weather, the pinning blankets which are furnished with all layettes. In every household where there is a baby, there should be at least one open fire where its feet may be occasionally toasted. No one can sleep healthily when cold, and the baby will rest much better if laid to sleep upon a warm blanket than between cold sheets.

HOUSEHOLD DIRT.—The dirt which may be wiped from the walls, swept off the furniture, and beaten out of the carpets of any ordinary house, would be sufficient, if it were sprinkled in the form of dust over the patients in the surgical wards of a great hospital, to bring all their wounds into a condition that would jeopardize life. It cannot be supposed that such dirt is innocuous when it is breathed or swallowed, and it certainly possesses the property of absorbing and retaining for long periods, the contagious matter given off by diseases. Instances without number are on record in which the poison of scarlet fever, long dormant in a dirty house, has been roused into inactivity by imperfect attempts at cleaning. The preservation of health is not a mere mechanical question of the perfection of any certain matters, but depends upon the intelligent avoidance of all the causes by which disease is liable to be disseminated.—*Decorators and Furnishers*.

TABLE OF CONTENTS.

EDITORIALS.—New Pumping Apparatus for Mines, 385. Passing Events; Electric Pumping in Mines; Mines in Town Sites; Fresno Mines; New Water Jacket Furnace; Rapid Tunnel Work, 392. Improved Amalgamator and Settling Tank in Mines, No. 12; Academy of Sciences; D'Arce's Comet, 393. Patents and Inventions; Notices of Recent Patents, 396.

ILLUSTRATIONS.—Huffer's Mine Draining Apparatus; Pump Arranged for Well, 385. The Decad of the Himalayas (Cedrus deodora), 390. Methods of Framing Round Timbers, 393.

MECHANICAL PROGRESS.—Seasoning Wood; What is Galvanizing; Electricity; Wet and Dry Coal in Making Steam; Grinding Pig Iron by Grain; A Difficult Thing to Understand; New Zealand Ironsands, 387.

SCIENTIFIC PROGRESS.—Some Examples of Chemical Synthesis; Light from Gas; Separating Citric and Tartaric Acids; How to Brighten Carpets; Formation of Arsenides by Pressure; Formation of Chemical Compounds by Pressure; New and Stale Bread; Luminosity of the Magnetic Field; Cooking, 387.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Meetings, Assessments, Dividends and Bullion Shipments, 388.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon and Utah, 388-9.

USEFUL INFORMATION.—The Manufacture of Watches; Water Glass in Paint; Melting Iron with Copper; Fence Posts that will Last; A New Invisible Ink; Hemlock Timber; Needles and Pins; Ebonizing; Luminous Paint in Railway Carriages; To Clean a Watch; To Polish Steel, 391.

GOOD HEALTH.—Sleeplessness; Practical Hints about Glasses; Pneumonia; Warm Bed Clothing for Children; Household Dirt, 391.

MISCELLANEOUS.—Mining Dividends; Smelting Ores; Thoughts on Prospecting; Gold, Silver, Copper; The Waterwheel Trials, 388. The Coterie of the Gods; Wood River; Snake River Placers; Leaching Works, 390. A Bright Outlook at Safford District, 391.

NEWS IN BRIEF—On page 396 and other pages.

BUSINESS ANNOUNCEMENTS.

Assessment Notice.—Seaton Gold Mining Co., S. F. Dividend Notice.—Standard Con. M. Co., S. F. Trinity School.—Rev. E. B. Spaulding, S. F. Engines.—J. M. Lakenan, Grass Valley, Cal. Mills Seminary.—Rev. C. T. Mills, Alameda Co., Cal.

Passing Events.

The exceedingly warm weather which has prevailed in this State, this week, is somewhat phenomenal. In San Francisco the thermometer ranged higher than it has since the Signal Service station was established here. It has been over 100 degrees in the shade. In many parts of the State the hot weather has been experienced for several days.

There is little now to report from the mining regions other than we have noticed in our usual summary. Both Montana and Idaho are just now attracting a large share of attention, and many new mines are being opened. The railroad connections now established with several of the prominent camps will give mining affairs a "boom" up there this summer.

No encouraging news has been received from the Lower California mines, and it is probable, as we predicted, that the placers there will amount to little owing to scarcity of water.

Who says that Calaveras placer mining is played out? There is a man living at Railroad Flat who "pans out" between \$5 and \$6 a day. There is lots of gold in our gravel beds yet, only it is not hunted for quite as extensively as in the earlier days.—*Calaveras Chronicle*.

THE Grantsville Bonanza advises miners in search of work to keep away from Grantsville till they are certain active operations have been commenced.

LARGE quantities of ores of all characters and grades are now shipped from the districts existing from Benton south for 150 miles.

Electric Pumping in Mines.

There has been a great deal of talk about the application of electricity as a motive power in mining operations, but few know that practical employment of the force has been made on working pumps in mines. This has been done however, at the Trafalgar colliery in the far famed Forest of Dean, where Mr. William B. Brain, one of the proprietors has applied electricity in a way to interest all mine owners. The generator and engine are on the pit bank. The machines are sufficiently portable to be carried about by a single individual, and, nevertheless, might be worked up to several horse-power. In connection with it are a couple of cables which are carried down the pit shaft. Suspended in one of the corners of the engine shed are two instruments—the "Ohm meter" and "Volt meter," answering to the steam gauge of the engine boiler. These show the amount of electric power being generated by the dynamo machine. Mr. Brain has adopted a simple device which indicates, approximately, the amount of electric power being generated without reference to meters at all. By introducing a couple of miniature incandescent lamps (Swan's or Edison's) and by looking at the amount of light they emit, the man in charge is able roughly to determine whether the electric force being generated is up to the requirements or otherwise, and he regulates the steam engine which drives the dynamo accordingly.

The electric pumps are in small chambers in the mine. The electric fluid is, as stated, brought from the surface to the pumps by cables, or stout insulated wires. The pump works thirty-two strokes per minute, and can throw a gallon stroke up a vertical height of ninety feet. It is pointed out that the electric pump was provided to meet a special difficulty, and here hinges an illustration of the great usefulness of the new power. There was only a small quantity of water at this point of the working, but in order to prevent its descending through the measures into lower parts of the colliery the electric pump was introduced, and, as already proved, with very great success. Small as it may be admitted is the actual utility of the pump in a colliery such as this, where large bodies of water have to be dealt with, nevertheless, from a mining point of view, it represents thousands of pounds. At Trafalgar, as in hundreds of other collieries, there are identical circumstances, where at various points water has to be either caught or allowed to proceed down the workings to other points. By contrivances such as the present one, the difficulty is economically and readily compassed, as the machine, when once started, continues without attention, except occasional oiling two or three times a day. In the present instance, the engine on the bank is sufficiently powerful to work a dozen such machines as the one described, and Mr. Brain is making arrangements to replace other pumps at various stations in the colliery, with electric pumps, and the firm will thus get rid of a heavy detail of cost in the working expenditure. As compared with the old system, the saving in wear and tear is considerable. At 1,000 yards from the shaft is a donkey engine and boilers and pumps; these will be shortly superseded by one of the new machines.

This mine has gaslights all through its galleries. Telephones from the manager's office connect with instruments at the pumps and various stations, so if anything goes wrong it is instantly noted. The manager has also at the pump stations electric lights, which are kept burning by the same current which runs the pumps. The same engine on the surface runs a dozen or so of the small pumps. Apart from the application of electricity for the pumping of water and drainage of collieries, it is contemplated to employ electricity for winding the coal in the pit. A good deal of this, heretofore, has been done by horse power. At Trafalgar there are forty-eight horses employed in the colliery, and their first cost, as well as subsequent maintenance, is an important item in the profit and loss account. In one station a powerful engine is employed in drawing coals, and likewise provides the motive power for working of the main pumps. It was stated that the cost of the steel ropes alone from this station was between £300 and £400, and this was equal to the cost of laying down the electric station and appliances already described, and that, moreover, there was a heavy cost involved in the wear and tear of lengthy ropes as employed. There are electric signals throughout the colliery, and the further experiments being made there are of the utmost importance to mine owners all over the world.

NEVADA COUNTY BULLION.—In the abstract of the report of the Director of the U. S. Mint as telegraphed to this coast, Nevada county, of this State, is only credited with some \$300,000 yield. The North Bloomfield, Milton and Enreka Lake hydraulic mines, on one ridge alone, a mere ink stain on the map of the county, produced double that amount, and the aggregate of two quartz mines would certainly aggregate all the county is credited with. It is probable a typographical error has occurred and that \$3,000,000 instead of \$300,000 was intended by the Mint Director, since Nevada county is, and has been for many years, our center of gold mining in this State.

Mines in Town Sites.

There have been a number of cases of litigation concerning the right of miners to mines on patented town sites. The great change which introduced an entirely new system of mining laws, differing from that of any existing government, was made by the Act of July 26, 1866, and it gave, with certain restrictions, legislative sanction to the laws and customs of "local authority" affecting possessory rights and the added privilege of acquiring title to the mine itself under the authority and forms of law. This change gave such rights, even against the government, as required modification of the town site provisions and resulted in the enactments of 1867 and 1868, with express reservations against the acquisition of mines or valid mining claims. The Revised Statutes now contain the several provisions with the subsequent amendments of the mining laws. The law first granted the town right, and afterwards abridged it only so far as to admit the new relations presented by the enactment of mining statutes, and the reason of the whole seems to result in this, according to the Secretary of Interior, who rules that by the acquisition of title to a town site no right remains to proceed for patent for mining ground under the reservations of law, except:

1st. For the mines, with only such incidents of surface ground and the like as are actually necessary to the use and operating of the same; and

2d. For such mine and possessory rights, including surface ground not in excess of that recognized by law at the date of location, as were acquired by the applicant or his grantors, privies in interest, before the legal inception of the patented town right.

But as with the grant of mines, the power to dig them is impliedly given, so the reservation of mines the power necessary to their enjoyment must be also reserved; and this reservation to and by the government must inure under the mining laws to citizens of the United States authorized to explore and possess them, and acquire the government title thereto.

If then, an applicant seeks to acquire patent for a mine (lode or vein), within a patented town site, based upon a location subsequent to such patent, he must be required to show affirmatively the existence of such mine and its true location, and prove his possessory right and value of work performed, as in other applications. He will not, however, be permitted to proceed as for a claim with surface claim, limited only by the usual statutory restrictions as to width along the vein, but will only be allowed to claim the necessary surface ground for the convenient working of his mine, in no case in excess of the legal width at date of the town-site appropriation. His plat must distinctly show the ground so claimed with relation to all other claims and the occupation and improvement of others, whether municipal or otherwise—and proof of such necessary possession and use must be furnished sufficient to make a clear *prima facie* showing of his right.

If such showing he made he may proceed to publication, and if no adverse claim is filed may obtain his patent, containing the usual town-site reservations, for the protection of any interest previously acquired.

Fresno Mines.

We are told that Messrs. Litchfield & B. F. Jones have leased the Texas Flat mine in Potter Ridge district, Fresno county, for two years, and afterwards get a bond on the mine during the period of the lease, the bond being for \$10,000 and 3,000 feet of ground. The mine has been rich in the croppings and was worked down until the pay body gave out, the lead having been lost. They started an incline down on the vein, the ore then gave out, but left a fine ledge matter. Search for an ore body had been pursued for some years on the surface, and all other places with the exception of the right one.

Messrs. Litchfield & Jones in commencing work cleared the incline of the debris, went down from fifteen to twenty feet and struck as fine a body of ore as was ever struck in Fresno county.

They continued to sink the incline in the ore for forty or fifty feet, and the ore has the same appearance on all sides and bottom. The ore contains a large percentage of sulphurets, of which the percentage runs from seven and a half to twenty-five per cent. The lowest assay averages \$153.75 per ton, but some very high assays have resulted from tests of the rock.

Among other mines of the neighborhood are the Fresno Flat Enterprise, Jim Lang, where they are building a mill, Last Chance, where there is a mill, and Spangle, which has a small but rich ledge. All these mines are working on excellent showing.

New Water Jacket Furnace.

Water jacket smelting furnaces are now used very extensively on this coast, for smelting copper and lead ores and their number is rapidly increasing. An improvement on this style of furnace has just been patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by John H. Canavan, of Globe, Arizona, by which the walls of the furnace are kept cool with the use of less water than usual, and the inventor claims, some 20 per cent less fuel. For convenience the upper half of the furnace may be made of cast-iron, with the tuyere-pipes cast on the inside, and it may be bolted to the lower part. This jacket is intended to be used both for water and for air, the water occupying the lower part, and the air, which is to be employed as a blast, being introduced into the upper part above the surface of the water through the blast-pipe. This pipe enters near the top of the exterior casing of the jacket, and, being bent sharply downward between the walls of the jacket, extends nearly to the bottom of the air-space.

The pipes connecting with the tuyeres, extend up to near the top of the jacket, so that the air which is discharged from the lower end of the pipe, must rise between the walls of the tuyere, where it is heated before it enters the tuyere-pipes, and a hot blast is thus produced to be discharged into the furnace. This current of air at the same time prevents the walls of the furnace at the upper part from becoming too much heated, while the water protects the lower part.

When the furnace is to be worked, water is admitted by an inlet-pipe, into the water-chamber in the lower part of the jacket, and is also admitted into the air-space through a cock, so as to rise to the level of another cock through which any surplus may be allowed to overflow. This water in the air-space remains as long as the air-blast is not used and protects the upper part of the furnace from too great heat. When the air-blast is to be admitted the cock at the bottom of the air-space is opened and the water allowed to run out. The air from the blast apparatus is admitted through the pipe and is discharged close to the bottom of the air-space of the jacket, whence it rises to near the top and is heated by its contact with the wall of the furnace before entering the tuyere-pipes. These pipes convey it down to the tuyeres, through which it is discharged into the lower part of the furnace. The water in the lower part and the blast of air passing through the upper part keep the walls of the furnace sufficiently cool without the necessity of keeping the whole jacket full of water. Whenever the blast of air is shut off water may be again admitted to the air-space.

Rapid Tunnel Work.

Some exceptionally rapid work is now being done by the Barleigh drilling machinery employed at the Big Bend tunnel, in Butte county, in this State. The following figures, showing progress for the month of May, will be of interest to miners:

Total number of holes drilled, 1,128; total depth of holes drilled, 7,033 feet; average depth of holes drilled, 6.25 feet; number of pounds of No. 1 powder used, 3,700; number of pounds of No. 2 powder used, 50; number of drills sharpened, 820; time occupied in drilling, 155 hours and 10 minutes; average time per shift, 1 hour and 40 minutes; number of carloads of rock extracted, 3,690; tunnel advanced for month, 360 feet; previously reported, 1,742 feet; total tunnel built to date, 2,102 feet; total number of shifts in month, 93; average progress per shift, 3.87 feet; average progress per shift, 24 hours, 11.61 feet; number of working days in month, 31; number of working shifts in month, 93.

Gov. TRITLE, of Arizona, says that Tucson shows the enterprising spirit of its people in the numerous enterprises projected and under way. The Board of Supervisors of that county has recently donated \$15,000 for the erection of a smelter and reduction works there and had carried out as far as they were concerned the provisions of the acts passed at the last Legislature, providing aid in the shape of bonds for the construction of two additional railroads. One is the Port Lobos, to be built from Tucson to the Gulf of California. The other is a narrow gauge, and will be built in the direction of Globe; hence it is contemplated by the aid and co-operation of Maricopa county to extend it to Phoenix.

THE coinage of the various mints for May was \$4,721,200, of which \$235,000 were standard dollars.

Improved Amalgamator and Settler.

A peculiar amalgamator and settler has just been patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by Frederick Morris, of this city. It is made mostly of wood. A wooden platform is prepared having a central vertical post secured to it by bolts passing down through said post and platform. Around this post, on the platform, are fitted segmental blocks, forming a plate or disk, which is the bottom of the amalgamator or vessel. These blocks are nailed down to the platform. This construction is intended to obviate any shrinkage. The sides of the vessel are made of staves, the lower ends of which are nailed to the peripheries of the blocks forming the bottom. The staves are secured together by wooden hoops.

On the bottom of the vessel are laid segmental blocks or dies, which, by being made shorter than the blocks forming the bottom, leave a peripheral channel or groove. Their sides are also provided with thin strips, whereby they are separated sufficiently to form shallow radiating grooves. On the top of the central post is a cap which serves as a stop or bearing for a vertical shaft, which is journaled therein. On this shaft is the cross frame of the muller, in the arms of which are secured rods extending down within the vessel, nearly to the blocks. On these rods are loosely fitted the miller shoes or blocks, which pass along the bottom and adjust themselves vertically on the rods. A weight is placed on each shoe to keep it down to its place. The muller is revolved by a crown gear on top of the shaft, with suitable connections.

The device is for settling ore pulp in order to separate the heavy particles from the mud and slime after the ore has been ground. The revolving muller keeps the pulp agitated. The waste after separation is gradually forced to the center where it escapes. Two holes are made through the central post and platform which carry off the waste into a channel under the platform. These holes are not made at the very top of the post, but on a small ledge cut out nearly at the top. The escapes are easy to make and being right at the center and top, none, but the worthless part which has been fully separated and has risen to the top, will be discharged. The whole device is simple and economical and is put together in such a manner as to render it water-tight and durable.

White Pine Mines.

The condition of the mines at the old camp of Hamilton, White Pine county, Nevada, has much improved of late. The Sweetwater mining company, a New York corporation, has leased the "Old Saoky" mill, spent \$25,000 in new machinery and improvements, and has leased the water works from the Eberhardt & Aurora company to run it. This company has its second regular pay day on the 10th, and disbursed then \$7,000 among the employees, of whom there are at present thirty in their mines, and as many more in the mills. In the Stafford mine there is ore enough to keep the mill running for at least a year without any further prospecting, and there are 506 tons on the dump and at the mill.

Two large ore wagons are to be kept constantly running from the mines to the mill with ore.

At the Eberhardt and Aurora tunnel there are twelve men employed, and some fine quality ore is being brought out of it. Over 12,000 feet of tunnel, drifts and cross-ends have been made, and the pluck and perseverance of this company will doubtless be productive of good results. The general opinion prevailing in the camp is to that effect.

There are several small mines being opened by their owners, and more or less ore extracted. Now that the means to reduce ore cheaply will be furnished, a general revival of the mining interests in this once famous locality is confidently expected.

The Jenny A. mine, on White Pine mountain, is a very extensive and valuable property. There are immense deposits of low grade ore in sight, and rich ore in smaller quantities. The Superintendent, however, has been absent several months. With a proper amount of capital and necessary reduction works, which it is hoped will be supplied through the efforts of Mr. J. R. Kendall, the Jenny A. property will prove one of the best mines in the country.

At the Kennisbury mine there are ten tons of ore on the dump that will average \$300 per ton in silver. Some very fine ore is coming from the Hope mine and there are several others that are coming to the front as ore producers.

Timbering in Mines—No. 12.

If the sides of the roadway are strong, and the roof alone weak, the latter may be supported by timber resting upon the former. Such pieces are called head pieces, and they are let into the rock on each side, as beams are let into walls, to obtain a bearing. In thus placing the timbers, care is taken to give each piece sufficient and an even bearing at each end, so as to properly distribute the pressure. The distance of these pieces apart will, of course, be determined by the strength of the incumbent rock. To distribute the support of these pieces over the roof, and to prevent the fall of small portions of rock which become detached from the mass by atmospheric and other agencies, lagging is driven in between the head-pieces and the roof in a direction at right angles to the former. When slabs are used, the flat side is turned to the roof, in order to cover as large a surface as possible. Sometimes, especially in France, branches of trees are employed for this purpose, to form a network against the roof. The slab or planks are sufficiently long to reach at least from center to center

Fig 5. Fixing Timbers in Roof.

Fig. 1.

Fig. 2.

Fig. 3.

METHODS OF FRAMING ROUND TIMBERS

ter of two head-pieces, but it is better that they should rest upon three of these supports. To distribute the pressure equally over the headpieces, wedges are driven in between them and the roof wherever a space exists. The mode of inserting the headpieces will be understood from a reference to Fig. 5 of the accompanying engravings, which shows a plan of a drift with roof removed; in other words looking down on it. A hole or notch A is cut into the side rock near the roof, to a depth sufficient to give the requisite bearing, and made slightly broader than the timber to be inserted, in order to allow the play required by the operation. On the opposite side of the excavation, a similar hole B is cut; but the fore side of the hole is cut away in the manner shown in the figure, for the purpose of allowing the headpiece to be inserted. The mode of introducing the headpiece is shown by the dotted lines. Before, however, the end has been thrust into its definite position, a wedge is placed at *u*, with its thin end outwards, and against this the headpiece is driven until a sufficient degree of tension has been given to it.

It may sometimes happen that one side of the excavation, as well as the roof, needs support. In such a case a method of half timbering is adopted. A hole, similar to that at A, in Fig. 5, is cut into the side roof, to receive one end of the headpiece, or cap, as it is frequently termed.

A shallow is also cut in the floor, to receive the end of the timber that is to stand vertically on that side. This vertical piece is variously described as "upright," "leg" or "stanchion." The stanchion is set in an inclined position in this

hole, usually with its smaller end downwards, and the headpiece having been placed with one of its ends in the hole in the rock, cut for it, and its upper end resting upon the upper end of the stanchion, the latter is driven into the vertical position. By this means sufficient friction is developed to hold the two pieces firmly together. If, however, in consequence of the yielding of the floor, or a miscalculation in the length of the stanchion, this friction is not obtained, wedges must be driven either beneath or above the stanchion.

As it is desirable not to weaken the timber by notches or any unnecessary cuts, care will be required in preparing the bearing surfaces. In most cases these surfaces will be held together by friction alone, and two methods of preparation may then be adopted. In one the lower side of the cap is cut away with the axe in a slight degree, so as to give a flat bearing surface. The upper end of the stanchion is in this case cut off square. In the other method, the upper end of the stanchion is hollowed out to receive the round surface of the cap. These methods, as used with round timbers are shown in Figs. 1 and 2.

Whatever be the method adopted, it is important to make the cap bear evenly upon the stanchion, so as to avoid any tendency to split the pieces when the pressure comes upon them. Sometimes the lateral pressure from the sides of the excavation will be greater than the down-

Fig. 3.

Academy of Sciences.

At the regular meeting of the Academy, on Monday evening last, Hon. Chancellor Hartson was elected a resident member. Rolt, E. C. Stearns, Ph. D., read a paper "On the Molluscan Fauna of the Colorado Desert and Regions East Thereof." He first spoke of the extinct phylas, or fossil pond snails, found at Indian station, on the Southern Pacific railway, and of the fresh water mussel shells of the same region, commonly called the *Anodonta Californiensis*. He said the Colorado basin was once a great lake or series of lagoons, 150 miles in length, some portions of which are now 1953 feet below the ocean level. This whole region bears marks of having undergone great depressions, and also great elevations between the middle tertiary and the close of the tertiary era—surely, before the early quaternary. This whole field of economic geology is an unworked one. *Physa*, meaning pouch, is applied to a family of fresh water shells. At Indian, San Diego county, they are found twenty-seven feet below the old sea line. Salt water shells found at a greater depth are older than the more recent fresh water forms. Similar shells are found on Santa Barbara Island, off the coast, indicating that formerly a connection existed between the head of the Colorado basin and the Santa Barbara channel. In dry regions these shells are white, and in wet places they are darker externally.

Colonel George E. Gray, Chief Engineer of the Southern Pacific Railroad, said at one period the waters of the Pacific Ocean flowed beyond Indian station, and the waters of the Gulf of California extended far inland along the Colorado basin. Marks of a submergence extend over a large area, and subsequently a sedimentary filling up was deposited in the lowest localities. He thought a scientific examination of the old water line of the old Colorado basin or desert would develop many interesting facts likely to lead up to data of very general interest.

Dr. H. W. Harkness spoke of the disease affecting our sycamore trees, which now appears more general than at any time for twelve or fourteen years past. It results from the attacks of a fungus which kills the leaves and finally destroys the tree. This pest began in the Eastern States about the year 1739, since which it has made steady progress and threatens to exterminate the sycamore trees all over our continent.

John G. Lemmon and his wife, presented and explained 96 Arizona plants from the Huachuca mountains.

Professor Davidson made some remarks on D'Arrest's comet which we give in another column.

D'Arrest's Comet.

At the meeting of the Academy of Sciences on Monday evening, Prof. Davidson stated that as a matter of interest to astronomers Mr. Hind gives certain data which indicate that the chance of seeing the comet at this present visit is very slight indeed. On the 6th of June at Greenwich, mean midnight, the predicted right ascension of the comet is 13 hours and 9.6 minutes, and the north declination 12 degrees and 48 minutes, when its distance from the earth will be 190 millions of miles, and from the sun 243 millions of miles, whilst the intensity of its light will be only one fourth of the lowest value at which the comet has hitherto been observed. This low degree of light will continue to August, and then slightly increase until the end of December, when it will be three times brighter than in the summer months. And yet it is very doubtful whether it can be seen, especially as it will then set about two hours and eight minutes later than the sun.

The theoretical intensity of the light of a comet, considered as unity, is represented by the reciprocal of the product of the squares of the distances of the comet from the earth and from the sun.

So far the search for the comet has been unsuccessful, and Mr. Common reports that with his larger reflector he has been unable to find it; but he notes the surprising number of faint nebulae which are lying along its predicted track.

This comet is one of the short period comets, having a period of 6.44 years, and an aphelion distance of 5.75; and thus belongs to the group of comets and meteor streams whose aphelion distances are near equal to the radius of the orbit of Jupiter (5.20). It was observed in 1851, 1857, 1870 and 1877.

The orbit of this comet almost intersects that of the lost comet of De Vico, in heliocentric longitude 33° 37', and with the elements of 1851 the distance between the orbits was only 507,000 miles.

De Vico's comet is another of the short period group with a period of 5.49 years, and an aphelion distance of 5.02, or within the orbit of Jupiter.

The prosperous Colorado mining town, Chaffee City, will, after July 1st, be known as "Monarch" upon the official postal guide. The Postmaster General has, upon the request of the miners, ordered the change to be made. The mineral developments in the vicinity of Monarch are unusually large and promising, and investors are looking that way.

JOHN H. MARTIN, of Oroville, Butte county, in this State, inventor of an improved hydraulic elevator for working gravel mines, has left for Gunnison City, Colorado, under an engagement to a company of capitalists, who intend to open and work hydraulic mines on the Gunnison river, within the limits of the Indian reservation, where Colonel Thornburg and Agent Meeker met their fate.

MR. ROLCKER, late Superintendent of the Chrysolite mine, Colorado, and lately employed in the interest of the Copper Prince, Arizona, has gone to Sonora to inspect some prospects for New York parties.

Metallurgy and Ores.

Nevada Metallurgical Works,

No. 23 STEVENSON STREET,
Near First and Market Streets, S. F.
ESTABLISHED, 1869. C. A. LUCKHARDT, Manager.

Ores Worked by any Process.
Ores Sampled.
Assaying in all its Branches.
Analyses of Ores, Minerals, Waters, Etc.
Working Tests (Practical) Made.
Plans and Specifications furnished for the most suitable process for working Ores.
Special attention paid to Examinations of Mines, plans and reports furnished.

C. A. LUCKHARDT & CO.
(Formerly Hubn & Luckhardt.)
Mining Engineers and Metallurgists

JOHN TAYLOR & CO.,

IMPORTERS OF AND DEALERS IN

Assayers' Materials, MINE and MILL SUPPLIES,

CHEMICAL APPARATUS AND CHEMICALS, DRUG-
GISTS' GLASSWARE AND SUNDRIES, Etc.

118 and 120 Market Street, and 15 and 17
California St., San Francisco.

We would call the attention of Assayers, Chemists,
Mining Companies, Milling Companies, Prospectors, etc.,
to our full stock of Balances, Furnaces, Muffles, Crucibles,
Scoffers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since
the first discovery of mines on the Pacific Coast, we feel
confident from our experience we can well suit the demand
for these goods both as to quality and price. Our
New Illustrated Catalogue, with prices, will be sent on
application.

Our Gold and Silver Tables, showing the value per
ounce Troy at different degrees of fineness, and valuable
tables for computation of assays in grams and grammes,
will be sent free upon application. Agents for the Patent
Plumbago Crucible Co., London, England.

8 CALIFORNIA STREET, SAN FRANCISCO.

Established 1864.

THE MOREY & SPERRY MINING MACHINERY CO.,

(Successors to MOREY & SPERRY.)

Manufacturers of all kinds of—

Mine and Mill Machinery

WAREHOUSES:

92 & 94 Liberty St., New York.

WORKS:

Newburg, New York.

The Foundry and Machine Shop (being open and aged) we are now prepared to
make from the most improved water-power QUARTZ and STAMP MILLS complete, for
working GOLD and SILVER ORES.

MOREY'S IMPROVED PULVERIZER,

For WET or DRY Crushing.

SIMPLE, EFFICIENT and DURABLE.

The Balls revolve horizontally without friction,
5 ft. size, weight 7,000 lbs., and does more work than 15
Stamps, 3 ft. size, weigh 3,000 lbs.
Concentrating Mills, Rock Breakers, Amalgamating
Pans and Separators, Roasting Furnaces, Hoisting and
Pumping Machinery, Engines and Boilers, any size
required, Hydraulic Giants and Pipe, Ore Cars, Ore
Buckets, Safety Cages, The Hand Power Two-stamp
Mill, weight 250 lbs. THE EUREKA WIRE ROPE
TRAMWAYS, Concentrating Riffles for Mills and Hy-
draulic Sluices.

Steel SHOES and DIES for Stamps, and Mine and Mill Supplies. Agents for IMLAY ORE CONCENTRATOR and the
MINER'S HAND ROCK DRILL. Information and Estimates cheerfully given. Send for Catalogue.
Address, THE MOREY & SPERRY MINING MACHINERY CO.

ANTI-SCALE COMPOUND

Manufactured by RICKARD & DURDEN.

We guarantee that, with proper use, this Compound will remove and prevent all
INCRUSTATION IN STEAM BOILERS.

Ten years trial, in widely separated localities, has demonstrated the value of this invention, and its applicability
to different qualities of water. References cheerfully furnished to any one wishing same.

TEN POUND SAMPLE BOX FURNISHED FREE ON APPLICATION.

BERRY & PLACE MACHINE CO., Sole Agents,
No. 8 CALIFORNIA STREET, S. F.

READY FOR DELIVERY.

LATHES, DRILLING MACHINES, PLANING MACHINES
And Other Machine Tools.

STRONG, DURABLE AND SUPERIOR TO IMPORTED MACHINES.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER.

Several first premiums received
for Quartz Mill Screens, and Per-
forated Sheet Metals of every
description. I would call special
attention to my SLOT CUT and
SLOT PUNCHED SCREENS,
which are attracting much at-
tention and giving universal
satisfaction. This is the only
establishment on the coast de-
voted exclusively to the manufac-
ture of Screens. Mill owners using Battery Screens exten-
sively can contract for large supplies at favorable rates.
Orders solicited and promptly attended to.
32 Fremont Street, San Francisco.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Grant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. **HALLIDIE IMPROVED ORE TRAMWAYS.** We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otto Steel. Workmanship the most careful. All Rivets Hand Driven.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

CONTINENTAL WORKS, BROOKLYN, N. Y.**Duc's Mechanical Atomizer or Pulverizer.**

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, FAYTES, COAL, OCHRE, MANGANESE, IRON ORES,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

THOS. F. ROWLAND, Sole Man'fr, Brooklyn, N. Y.**SELBY****SMELTING and LEAD CO.,**

416 Montgomery St., San Francisco.

Gold and Silver Refinery And Assay Office.

HIGHEST PRICES PAID FOR

Gold, Silver and Lead Ores and Sulphurets

Manufacturers of Bluestone.

ALSO, LEAD PIPE, SHEET LEAD, SHOT, ETC.

This Company has the best facilities on the Coast for working

GOLD, SILVER and LEAD

IN THEIR VARIOUS FORMS.

PRENTISS SELBY, - - Superintendent

WATER TANKS.

Over 700 of our well-known Water Tanks put in service last year. These tanks are made by machinery, from the best of materials, and shipped to all parts of the country. Each piece numbered. No skill required in setting up.

WELLS, RUSSELL & CO.,

MECHANICS' MILLS.

Cor. Mission & Fremont Sts., San Francisco

COPP'S U. S. MINERAL LANDS,

Laws, Forms, Instructions and Decisions.

Has no surplus verbiage. Contains Dr. Raymond's Glossary. Explains how to examine mining titles. Contains numerous court decisions. Gives the Public Land Commissions Codification, and gives many an improved form. Price—Full law binding, extra paper, \$6.00.

For Sale by DEWEY & CO., San Francisco

San Francisco Cordage Factory.

Established 1856.

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice.

TUBBS & CO.,

611 and 613 Front Street, San Francisco

WHITALL, TATUM & CO.,

NEW YORK. PHILADELPHIA.

—MANUFACTURERS OF—

CHEMICAL AND OTHER GLASSWARE.

CATALOGUES SENT UPON APPLICATION.

WIND MILL. One of the best made in this State for sale cheap on easy terms. Address, W. T., care of Dowry & Co., S. F.

**F. G. BECKETT,**

Manufacturer of

VERTICAL AND HORIZONTAL ENGINES AND BOILERS,

FROM 2 TO 90-HORSE POWER.

Improved Hoisting Engines, Engines for steam Yachts. Engines for pumping artesian wells and irrigating and farming purposes, and all kinds of Machinery.

Repairing Promptly Attended to.

No. 44 FIRST STREET. SAN FRANCISCO. CAL.**LORD'S****Boiler Cleansing Compound,**

For the prevention and removal of Scale in Steam Boilers, and for Neutralizing Acid, Sulphur and Mineral Waters.

Important safeguard and remedy for all users of steam. For Circulars and all information regarding its use, please apply at office of the Agents.

JOHN TAYLOR & CO.

118 & 120 Market and 15 & 17 California St., San Francisco

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First St., a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. Reference as to above can be had upon applying to this office.

N. W. SPAULDING'S

Manufacturer of all kinds of Chemical Stoneware —FOR— Manufacturing Chemists. Also Chemical Bricks for Glover Tower.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in Dewey & Co.'s Scientific Press Patent Agency, 252 Market St., S. F.

- FOR WEEK ENDING MAY 29, 1883.
- 278,482.—DREDGER CHAIN—H. R. Angell, S. F.
278,652.—CASTING STEROTYPE PLATES—Chas. Bachelder, Portland, Oregon.
278,405.—CARPENTER'S BEVEL—Cummings & Van Amringe, Oakland, Cal.
278,317.—LIFFING JACK—Jas. Dawson, S. F.
278,325.—DRY ORE CONCENTRATOR—W. B. Farwell, S. F.
278,422.—TUCKER ATTACHMENT FOR SEWING MACHINES—Fisher & Hart, S. F.
278,355.—APPARATUS FOR MAKING CARBON PLATES—Molera & Celvian, S. F.
278,451.—VALVE GEAR FOR STEAM ENGINES—E. O'Neill, S. F.
278,607.—AUTOMATIC HANGING UP ATTACHMENT FOR LABEL VARNISHING MACHINES—Schmidt & Rahskopf, S. F.
278,612.—FLUOR PLUGGING DEVICE—F. Sharp, Los Angeles, Cal.
278,474.—HARNESS COUPLING—L. Wartenberg, Anaheim, Cal.
278,632.—HARROW—J. A. Thronson, Daton, W. T.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press American and Foreign Patent Agency, the following are worthy of special mention:

DREDGER CHAIN.—Horace B. Angell, S. F. No. 278,482. Dated May 29, 1883. This invention relates, generally, to improvements in drive chains of that class in which the ends of adjoining links are pivoted upon and connected by a transverse pin; and these improvements are applicable to chains used in dredging machines for elevating the buckets and lowering them again to their work. Chains of this class are exposed, in addition to the ordinary wear caused by the longitudinal strain of one link upon another, to the destructive grinding action of sand and other gritty substances, which work their way into the joint between the links, and in a very short time destroy the bearing surfaces. When these links are connected by a simple steel pin, it has been found that in a very few days the wear causes the joint to work loose and in a short time become unfit for use. Attempts have been made to remedy this difficulty, by surrounding the pin with a tubular bushing of hard steel, which could be renewed when worn out. It was found, however, that the wear upon this bushing was so great and so speedy, that there was necessity for continual renewing of the bushing at some point or other in the length of the chain, and the utility of the chain was thereby greatly lessened and the expense, not only of manufacturing but of keeping it in repair, correspondingly increased. Mr. Angell's invention consists in a peculiar sectional bushing interposed between the pin and the bearing surface of the link, each section of which shall be of such a width as to cover the bearing surface of the eye within which it is held.

VALVE GEAR FOR STEAM ENGINES.—Eugene O'Neill, S. F. No. 278,451. Dated May 29, 1883. These improvements in valve gear consist mainly in a mechanism by which the eccentrics actuate the valves, and in an improved construction of the valves and their seats, and also in a means for connecting the exhaust valve stem with the actuating levers. In the mechanism already patented by Mr. O'Neill, the steam and exhaust valves are both operated from above by suitable stems; but the stems of the exhaust valves pass up through hollow sleeves, and their seats must be removed through the top, thus requiring considerable work when it is necessary to gain access to the exhaust valves. In the present invention, each steam valve has a stem passing up through the top of the steam chest, and connected with the actuating mechanism. The exhaust valves have stems which pass downward through stuffing boxes at the bottom.

CARPENTER'S BEVEL.—James B. Cummings and B. F. Van Amringe, Oakland, Alameda Co. No. 278,405. Dated May 29, 1883. The invention relates to that class of carpenter's instruments or tools known as "bevel squares," and it consists in a blade pivoted in each end of the slotted stock, and in the formation of the ends of said blades. The object is to combine in one instrument two blades, so formed and capable of such adjustment as to answer the purpose of two separate bevels and a square in the most convenient manner.

THE mines at Gold Park still remain closed down.

THE feeling of languor and debility that follows physical exertion, removed by using Brown's Iron Bitters.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walked with aquaria constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

Meetings and Elections.

CHOWN POINT G. AND S. M. Co.—June 5th. Directors: C. L. Weller, President; R. P. Morrow, J. P. Jackson, A. K. P. Harmon, and J. H. Dobinson. James Newlands continues as Secretary, and Sam. L. Jones as Superintendent. The company had a cash balance on June 1st of about \$22,000.

YELLOW JACKER M. Co. June 1st. The meeting of this company is thus reported by the Virginia Enterprise: The resignation of Joseph R. Ryan was read by Secretary Otey. George D. Edwards, of S. F., was elected to fill the vacancy. The resignation of R. H. Pollis was read. John W. Eckley was elected to fill the vacancy. The resignation of A. M. Cole was read. W. E. Sharon was elected to fill the vacancy. The resignation of Mercer Otey as Secretary was read by Secretary Otey. W. H. Blauvelt was elected to fill the vacancy. George D. Edwards was then elected as Vice-President. The Bank of California was elected Treasurer, vice the Nevada Bank. Captain Taylor continues as President and Superintendent. Serreta Otey will remain in the company's employ till the annual election (July 16th), to close up the year's accounts and initiate his successor.

Recent Contributions to the California State Mining Bureau.

[Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY C. HANSEN, State Mineralogist.]

[CATALOGUE.]

4924. Silver Ore—Mina de Prais, State of Tolima, U. S. de Colombia, S. A. Carlos Faulhaber. This is an old Spanish mine reopened in the year 1882. It has given large returns to the owner, but belongs now to an English company. The ore body on the 500-foot level is 18 feet across. The ore is crushed in the mine and sent to England for reduction.

4925. Silver Ore—Mina in Pava, State of Cauca, U. S. de Colombia, S. A. This mine was started fourteen years ago. It is not worked with any system, but has yielded a great deal of silver. The reduction is by barrel amalgamation. Carlos Faulhaber.

4926. Silver Ore—Mina in Soledad, State of Antioquia, U. S. de Colombia, S. A. This is a new mine; ore vein three to four feet broad, and but little work being done on it. Carlos Faulhaber.

4927. Silver Ore—Mina Guadalupe, State of Cauca, U. S. de Colombia, S. A. This is a very large mine, is well opened, and is beginning to pay well. Carlos Faulhaber.

4928. Nelson's Island (London). Recent Shell, Viti Island, South Seas. Thomas Griffin.

4929. Crystallized Chumbar in Crystallized Calcite—Guaia Lupa mine, Santa Clara county, Cal. Henry May.

4930. Calcite, Technical Quartz, Piche, Lincoln county, Nev. Mrs. H. H. Day.

4931. Free Gold in Spar—Haver Hill Gold Mining Co., Thompsonville, Davidson county, North Carolina. J. Z. Davis.

4932. Conglomerate—Pioneer district, Gila county, Arizona. Charles H. Constock.

4933. Pebbles from the Harbor of Lubek, Baltic Sea, Germany. James Lechros.

4934. Anglesite (Sulphate of Lead) Sierra Mosado, Durango, Mexico. H. H. Ward.

4935. Chumbar, Santiago, Durango, Mexico. H. H. Ward.

4936. Tin Ore (Cassiterite) Cuernito, Durango, Mexico. Soil to be found in large quantities. Altitude of the mines, 12,000 feet. H. H. Ward.

4937. Rich Silver Ore—American Flag mine, Socorro county, New Mexico. Frank Drake.

4938. Rich Silver Ore—Yavahoe mine, Grafton, Socorro county, New Mexico. Frank Drake.

4939. Copper Ore (high grade), Silicate and Oxide, Chery, Chumbar and Chumbar. Frank Drake.

4940. Copper Ore (low grade). Yielding from three to five per cent of copper, but which can be smelted with a small profit. (See No. 4939.) Frank Drake.

4941. Iron Ore—Used as a flux in copper smelting. (See No. 4939.) Frank Drake.

4942. Calcite—Used as a flux in copper smelting. (See No. 4939.) Frank Drake.

4943. Copper Ore—Partly smelted in Water Jacket furnace. (See No. 4939.) Frank Drake.

4944. Slag—Formed in copper smelting with Water Jacket furnace. (See No. 4939.) Frank Drake.

4945. Copper Bullion—Containing 381 ounces of silver to the ton, obtained in Water Jacket furnace. (See No. 4939.) Frank Drake.

4946. Rock Specimens, 20 varieties—Sierra Madre, Durango, Mexico. Thomas Gilmore.

4947. Rich Silver Ore (Emballite)—Pintarch mine, Calico district, San Bernardino county, Cal. John Daggett.

4948. Rich Silver Ore, coated with Emballite—Garfield mine, Calico district, San Bernardino county, Cal. John Daggett.

4949. Silver Ore—Occidental mine, Calico district, San Bernardino county, Cal. S. Heydenfeldt, Jr.

4950. Silver Ore—Golconda mine, Calico district, San Bernardino county, Cal. Mrs. Townsend.

4951. Stone implement, supposed to have been used by the Indians in grinding and preparing paint—Found in a cave 150 feet deep, Calico district, San Bernardino county, Cal. Jas. Gould.

4952. Silver Ore—Veto mine, Calico district, San Bernardino county, Cal. Charles Kaufman.

4953. Barite (Sulphate of Barium)—Calico district, San Bernardino county, Cal. S. Heydenfeldt, Jr.

4954. Silicate (Gypsum)—Calico district, San Bernardino county, Cal. S. Heydenfeldt, Jr.

4955. Ulexite (Borate of Lime)—Fish Lake valley, Esmeralda county, Nev. W. D. Linton.

4956. Ulexite, variety usually called "Sheet Cotton," containing Boracic Acid—Death Valley, Inyo county, Cal. J. Danvers.

4957. Borax—Made from Ulexite (Borate of Lime) decomposed with Carbonate of Soda. J. Danvers.

4958. Porphyriferous Rock—Near Soledad, San Diego county, Cal. W. C. McDonald.

4959. Slate—Near Red Hill, Butte county, Cal.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

- G. W. McGrew—Santa Clara county.
M. P. Owen—Santa Cruz county.
J. A. W. Wright—Merced, Tulare and Kern counties.
JARED C. HOAG—California.
B. W. CROWLEY—Arizona Territory.
N. H. BARRETT—Phonax county.
M. H. JOSEPH—Eureka, Nev.
L. M. LEWIS—Los Angeles, San Bernardino and San Diego counties.
A. C. KNOX—Oregon and Washington Ter.
F. W. STRATTON—Sierra and Yuba counties.
J. J. BARRETT—Yolo county.
JAMES W. BOYER—Sacramento county.

COMPLIMENTARY SAMPLES of this paper are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times,) by turning a leaf.

News in Brief.

BISMARCK has been chosen as the capital of Dakota.

SAN FERNANDO is to build a new and elegant school house.

HANLAN, the famous oarsman, is coming to California in September.

THE San Joaquin Valley Agricultural Association will offer \$30,000 in premiums this year.

THE Geyser stage capsized the other day, going down the grade with a lot of passengers, but no one was hurt.

A CYCLONE did considerable damage in Texas and Alabama Sunday. Several persons were killed and much property destroyed.

OKANSHI is the name of a new watering place just laid out on the line of the California Southern railroad, in San Diego county.

BURCHARD, Director of the Mint, left Washington Saturday upon an official visit to the mining regions of the Western States and Territories.

It is stated that the railroad company will try the experiment of making its cars at Seattle, W. T., with a view to establishing a manufactory there.

THE *Belgarica* left Queenstown Thursday with 700 State-aided emigrants, and the *Phonix* left Glasgow on the 30th with 290 of the same class of passengers.

THE rainfall during the last month was phenomenal, being 3.52 inches. The nearest approach to this figure during fourteen years was in 1879, when 2.35 inches of rain fell.

THE members of the Salvation Army have been notified by the Chief of Police of New Haven, Conn., that they must stop street singing in future, under penalty of arrest.

It is whispered that the engineers, conductors, brakemen and other employees of the Northern Pacific west of San Antonio, are organizing a strike on account of a recent ten per cent reduction.

THE new grain wharf at Port Costa will cost \$250,000; employs 175 men in its construction; will be finished by July 1st; 320 feet will be utilized as a warehouse, capable of storing 100,000 tons of grain.

New Life

is given by using BROWN'S IRON BITTERS. In the Winter it strengthens and warms the system; in the Spring it enriches the blood and conquers disease; in the Summer it gives tone to the nerves and digestive organs; in the Fall it enables the system to stand the shock of sudden changes.

In no way can disease be so surely prevented as by keeping the system in perfect condition. BROWN'S IRON BITTERS ensures perfect health through the changing seasons, it disarms the danger from impure water and miasmatic air, and it prevents Consumption, Kidney and Liver Disease, &c.

H. S. Berlin, Esq., of the well-known firm of H. S. Berlin & Co., Attorneys, Le Droit Building, Washington, D. C., writes, Dec. 5th, 1881:

Gentlemen: I take pleasure in stating that I have used Brown's Iron Bitters for malaria and nervous troubles, caused by overwork, with excellent results.

Beware of imitations. Ask for BROWN'S IRON BITTERS, and insist on having it. Don't be imposed on with something recommended as "just as good." The genuine is made only by the Brown Chemical Co. Baltimore, Md.

Mining Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

Seaton Gold Mining Company.—Location.

Principal place of business, San Francisco, California. Location of works, Drytown, Amador county, California.

In accordance with law, and an order of the Board of Directors, made on the 10th day of April, 1883, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at 528 California St., Room 6, San Francisco, Cal., on THURSDAY, the 5th day of June, 1883, at the hour of 1 o'clock p. m., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expense of sale.

A. MARTIN, Secretary.

OFFICE—Room 6, 528 California St., San Francisco, California.

POSTPONEMENT.

The above sale of delinquent stock is hereby postponed to THURSDAY, the 28th day of June, 1883, at 1 o'clock p. m., at the same place. By order of the Board of Directors.

A. MARTIN, Secretary.

San Francisco, June 6, 1883.

DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company.

San Francisco, June 2, 1883.

At a meeting of the Board of Directors of the above named company held this day, Dividend No. 55, of twenty-five cents (25c.) per share, was declared, payable THURSDAY, June 12, 1883, at the Farmers' Loan and Trust Company, in New York, or at the office in this city.

WILLIAM WILLIS, Secretary.
OFFICE—Room No. 29, Nevada block, No. 309 Montgomery street, San Francisco, Cal.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurates, arsenurates, and gold and silver ores generally, with 120 lithographic diagrams. 1867. This work is unequalled by any other published embracing the subjects treated. Post-paid, \$7.50. Printed and sold by Dewey & Co., S. F.

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition, 1880), and the Extraction of their Respective Metals without Quicksilver. Illustrated, 156 pages. A valuable and carefully written work. Post-paid, \$3. Sold by Dewey & Co., S. F.

AARON'S LEACHING GOLD AND SILVER ORES.—The most complete hand-book on the subject extant, 164 pages (clavo illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical use in cloth, \$3. Sold by Dewey & Co., S. F.

THE EMPLOYER'S MINER'S AND METALLURGIST'S COMPANION, by J. S. Phillips, M. E., comprising a practical exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy, containing 672 Engravings and 33 Engravings. Price, bound in cloth, \$10.50. Sold by Dewey & Co., S. F.

MINING, ENGINEERING, MECHANICAL, FARMING, SCIENTIFIC, INDUSTRIAL AND NEW BOOKS in general can be ordered through Dewey & Co., publishers of the MINING AND SCIENTIFIC PRESS, S. F., at publishers' rates.

PHILLIPS' EXPLORER'S AND ASSAYER'S COMPANION (Third Edition). Price of Vol. 1, post-paid, \$6. Sold by Dewey & Co., S. F.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent.

"Challenge" Ore Feeders.

OVER 1100 HAVE BEEN IN SUCCESSFUL OPERATION.

Awarded First Premiums at the Preceding and last Industrial Fairs of the Mechanics' Institute of San Francisco.

TWENTY PER CENT. MORE ORE CRUSHED WITH FIFTEEN PER CENT. LESS WEAR OF IRON THAN BY THE OLD METHOD OF HAND-FEEDING.

The opposite cut illustrates two recently introduced O.P. and S. H. Attachments, which replace the Weight originally used and result in an obvious improvement.

The practical operation of the large number of these machines now in use demonstrates the fact that the principle upon which a perfect Ore Feeder must be constructed is that of a carrier and not that of a shaking table. Uniform feeding is not possible upon the latter plan. The ore must be gently carried upon a steady, advancing plane or table to the line or point of discharge, and there be simply dropped. Jerky or spasmodically acting contrivances will not answer the purpose for feeding wet or sticky ores, nor for the ores of mines where they may change from sharp quartz to an interstratified material of quartz and earthy matter.

The Feeders are in Successful Practical Operation in the Following Quartz Mills, and are giving Perfect Satisfaction to their Managers.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct, or if the paper should ever come beyond the time desired, be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time, we cannot be responsible for the errors or omission of agents.

EXCELSIOR BLASTING POWDER,

Manufactured by the

EXCELSIOR POWDER COMPANY.

This is no new, potent, non-explosive Safety Powder, but the Genuine Standard Nitro-Glycerine Powder, as safe to use and handle as any other. Nitro-Glycerine Powder manufactured. The fumes and gases, common in nitro-glycerine powders, are destroyed, and do not leave the miner with headache or nausea.

The powder is put up in cartridges of any size to suit the consumer, and is exploded in the same manner as all other high explosives; that is, by means of cap and fuse, or by electricity. It is not claimed for this powder that it is a non-explosive, or safer than other nitro-glycerine powder. All powder, and especially nitro-glycerine powder, should be handled carefully. The EXCELSIOR POWDER is as safe, and for strength far surpasses any other powder on the market. Address all orders to

EXCELSIOR POWDER COMPANY,

Room 9, No. 3 California St., San Francisco, Cal.

FOR SALE

By J. M. LAKENAN, of Grass Valley Foundry, Grass Valley, Cal.

One 20-inch bore engine, 24-inch stroke; one 18-inch bore engine, 40-inch stroke, Meyer's cut-off; one 14-inch bore engine, 36-inch stroke, Meyer's cut-off; one 12-inch bore engine, 30-inch stroke; two sets heavy pumping gear, with 100 and connecting rod irons, etc.; 450 feet of 16-inch pump pipe of 1-inch iron, heavy flanges; besides other mining and milling machinery.

For information, address J. M. LAKENAN, Grass Valley, Cal.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

THE BUCK THORN BARBED FENCE (One Piece Solid Steel.)

MILL & MINING MACHINERY.

F. A. HUNTINGTON,

No. 45 Fremont Street. - - San Francisco, Cal.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation. The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

F. A. HUNTINGTON'S

CENTRIFUGAL ROLLER QUARTZ MILL!

After running one of these mills on the Whidden mine, in El Dorado county, over four months, and thoroughly testing its capacity and durability, I am prepared to offer it to the mining public, and claim for it the following advantages over the drop stamp mill:

1. The cost of same capacity is not more than one-half that of stamps.
2. Freight to mine one-fourth that of stamps.
3. Cost of erection at mine one-tenth that of stamps.
4. It runs with one-third the power per ton of ore crushed.
5. The wear is less than that of stamps.
6. The wearing parts are easily duplicated.
7. It has a much better discharge, and leaves the pulp in better condition for concentrating.
8. It is a better Amalgamator, saving fully nine-tenths of the gold in the mill; the balance can be saved on plates in the usual manner.
9. It is continually crushing; not like the stamp, using power to suspend it in air ninety-nine one-hundredths of the time, and the balance making a thundering noise, and accomplishing comparatively small results. It is as far in advance of the stamp mill as the present method of making flour with improved rolls is over the Indian's mode of crushing corn in a stone mortar.

F. A. HUNTINGTON, ESQ.—DEAR SIR: Your Centrifugal Roller Quartz Mill has run on the Whidden Ool Mining Company's property, at Shingle Springs, El Dorado county, Cal., about four months, and it did good and satisfactory work; a greater portion of gold remaining in the mill than in a stamp battery.

Office, No. 502 Market St., UNION BLOCK.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR,

-OR-

VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrates are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

Room 7, 109 California Street,

DEWEY & CO'S

Scientific Press

Patent Agency.

(ESTABLISHED 1830.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

Number 24.

Timbering in Mines.—No. 13.

When both sides of the excavation as well as the roof are weak, which is the most common case, the form of timbering adopted will be similar to that shown in the accompanying engraving. Sawed, hewed or round timber may be used as convenient. In this case we have two stanchions, surmounted by a cap or head-piece, and the timbers are put together by notching or otherwise, according to circumstances. Generally, in levels driven by hand labor, the two stanchions are slightly inclined toward the axis of the excavation, so as to give a trapezoidal section, as shown in the figure. In such a case the timbers are not placed normally to the stratification, but their position is favorable to stability. One advantage of this position of the stanchions is the consequent reduction in the length of the headpiece, without a material lessening of the breadth of the excavation. As the headpiece is subjected to a transverse strain, the importance of this advantage is obvious. When the level is driven by machine labor the sides are vertical, and hence the stanchions will, in such a case, be placed vertically.

Sometimes the floor of the excavation as well as the sides and the roof is weak. This happens when the rock of the floor is of a soft nature. Where a soft floor has to be dealt with two points present themselves for consideration. One is the difficulty of obtaining a support for the stanchions upon such easily yielding rock and the other is the tendency of the floor to rise in the middle in consequence of the pressure on the sides. Some instances of these were recently given to the readers of the PRESS. This tendency is very marked in many of the under clays of the coal seams and it necessitates the adoption of means for its prevention, as otherwise the destruction of roadways goes on continuously. This means is found in completing the framing of the timbering by placing beneath the stanchions a piece similar to the cap above them. When the floor is only slightly weak these pieces may consist of half-round timber placed with the flat side downward; but if the tendency to rise is great whole timber must be employed. The upper surface is slightly cut down and, in some cases, notched with an ax to receive the lower ends of the stanchions. Slabs or planks will sometimes be required beneath these pieces, placed in the same manner as those above the caps, for the purpose of keeping the floor down.

RENO needs reduction works very much. There are hundreds of base metal mines around in the vicinity, but if the prospector finds one it is an elephant on his hands, solely because of the inability to have the ore reduced at any reasonable figure. Once assured that their ore could have a market, in less than two years hundreds of new mines would be worked.

TAYLOR district, Nevada, is just now attracting much attention. A town has been laid out, and some of the vacant buildings in Ward are being taken down and removed there.

THE new smelter at Battle Mountain, Nev., will be in running order in a very short time, and those owning mines close to town have begun shipping ore to be smelted.

MORE prospecting is being done now than at any other time in the history of Eureka district.

Silver Shoes and Dies.

We made brief reference a few weeks since, to the invention by Messrs. Johnson & Osborn, of Dos Cabezas, Arizona, of a new style of shoes and dies for amalga-

gamating pans, formed of silver. The silver amalgamates readily and presents a surface having a strong affinity for any particles of gold, silver or mercury, and will arrest the latter even when in its most difficult condition to save when it is finely divided or "floured." The

TIMBERING IN DRIFTS.

mating pans, and give now an engraving illustrating the application. The ordinary iron shoes and dies are subjected to considerable wear by the sharp sand passing between them,

shoes are represented at B, and the dies at A in the engraving.

In some cases the shoes are in the form of rollers which rotate as they pass over the dies,

SILVER SHOES AND DIES IN AMALGAMATING PANS.

and more or less iron is taken up with the amalgam, which is thus rendered base; and it is difficult to separate the gold and silver contained in it. The iron has, of course, no particular affinity for the particles of gold, silver or amalgam, and is of no assistance in arresting them.

Messrs. Johnson & Osborn propose as a new article of manufacture, shoes and dies for amal-

gamating pans, and the pulp is caused to pass between the surface of the rollers and the die, the great affinity of the amalgamated silver causing it to take up the passing valuable particles with great avidity. In this case the inventors think there is little need of the scouring or grinding action of flat shoes and dies. These shoes and dies may be used in what are known as "continuous pans" in which the pulp is fed in at the center

and is discharged continuously at the periphery of the pan. These silver shoes and dies add to the amount of silver by their wear, so absolutely nothing is lost, and there is no additional expense created to separate out base bullion afterwards. These shoes and dies form a new article of manufacture and may be practically applied quite readily.

The Lower California Placers.

The nature of the reports from the newly discovered placers of Lower California, is not such as would encourage men to leave their present work for the arid region in question. When this excitement first began, the PRESS stated that it was not likely to lead to anything but disappointment, since even if good placers are found, there is no water for the miners to work with. The gold mines that have been found in Lower California in time past have amounted to little on this account. When men have to pay fifteen cents a gallon for water to drink at the mines it follows there is not much use trying to work placer ground, and when this obstacle is added to that of great distance from civilized places, it is unlikely that the mines will amount to anything.

The men who have returned bring back very unfavorable reports of the mines and the regions, as the following, dispatch dated Guaymas, June 10th, shows: "The Joyce and Cashman party arrived to-day, after a hard trip to the placers. It took four days to cross the Gulf on our trip out, the distance being 111 miles to Trinidad Bay. Thence we went to the placers on foot, the distance being ninety-five miles, through a country devoid of vegetation and over a rough trail where water was very scarce. Nellie Cashman, with a party of five men, started from Trinidad Bay ahead of the rest of the party. Nellie and two of her party came near dying of thirst, but were rescued by the rest of the party overtaking them the second day out. When we arrived at the placers we found what there was of them completely worked out, Mexicans and Indians having worked them at least for one year. I saw over one hundred batches worked without a color. The placers are twelve miles from the nearest water, which is of inferior quality and which the Indians pack in and sell for 15 cents per gallon. From all appearances, inside of one month there will be no water nearer than the Mission San Gertrude, twenty-seven miles from the mines. We paid \$16 passage for ourselves and the same for our burros to cross the Gulf."

"SHEEP MOUNTAIN" is the name of a new mineral section in Idaho which is attracting many miners from Oda, Boise, Custer and Alturas counties. It is stated that the mines so far discovered give great promise for large returns over working expenses, though the country is yet comparatively isolated. The nearest route to Hailey is up Wood river to the head of Salmon river, and down the Salmon to the Middle fork. The mines were about 100 miles north of Hailey, or forty miles beyond Stanley basin.

THE *Southwest Sentinel*, New Mexico, says: Nearly the entire distance between Silver City and the new strike is covered with locations, and prospectors are in the field fifty miles beyond. The whole country is being scoured, and reports of finds are constantly coming in.

California Then and Now.*

After passing over a few miles of smooth, rolling hills clad with wild oak, alfileria, clover and mustard, our party of hunters descended into the fair valley of San Margarita, part of the princely estate of Don Juan Forster, and in a short time they reached the ranch-house itself.

The place is a relic of that golden age of California life which lay between the decline of the Missions and the invasion of the Yankee. Here still stands the old ranch-house, a great quadrangle of adobe, built around a courtyard, the seat of a little empire of 30 square leagues of land, much of it the very best in Southern California. The great walls, nearly a yard thick, hint strongly of cool days in summer and warm nights in winter. The long massive beams, cut in the mountains 30 miles away; the rafters lashed with raw-hide instead of being nailed; the old red tiles made by the Mission Indians and held in place by their own weight—all speak of the difficulties of building in those days. Yet the whole is massive and strong, and will stand for many a year to come when far more costly structures are decayed. Here still, as in bygone days, may be heard the whizz of the riata thrown by the skillful hand, for there yet linger a very few of that most extinct race, the old vaqueros of California—men who could, single-handed, ride down, lasso and bind the wild bulls of the hills on a mountain side, where a city rider would hardly dare to lead a horse.

Rude was their system of justice; but they had no probate courts or public administrators. They had no doctors or lawyers; but then they died without expensive assistance, and their families got at least 1% of the property they left. Living in true patriarchal style, surrounded by plenty of the solid necessities of life, with plenty of servants that cost only their board, with nothing to do but look after their herds, roll cigarettes, attend fandangoes and *meriendas*, and warble their beautiful language, they drifted down the stream of time without touching oar or rudder, or striking sand-bars or snags. That soft Arcadian day is gone. Its twilight still lingers in a few places, but its sun has set forever. Our countrymen came and were welcomed, for, contrary to the common belief, the majority of Californians were anxious for the change. We came with our usual Yankee conceit, and our prejudice against everything that comported not with our notions of "progress"—all strengthened by the prejudice against Mexicans imbibed during the war with them. We came to load them with ruinous costs and atrocious lawyers' fees to maintain those vested rights of property which all nations respect, to squat on their ranches and live on their cattle; to pass laws to destroy their only industry, and as time had proved, the best industry of this southern country. We came to lend them money at five per cent a month, and trap them into contracts to pay it for a long enough time to sweep away their homes with the mortgage. We came to turn up the parvenu proboscis at Indian-bred and Castilian-bred alike, and treated as "greasers" some who were our equals in every respect, and the superiors of many of the upstart Americans who sneered at them.

I do not believe that justice has ever been done to the Spanish of California, and this is not the only place to do it, even if I were fully qualified for this task. But such ideas as are generally obtained from newspapers and magazine articles about Texas and New Mexico convey a very false idea of the Spanish of California. Their names were written high upon the roll of honor of the State; and they have been among the best and most honest of State and county officials, and the most incorruptible and impartial judges. No more law abiding or better citizens existed than the upper half of the Spanish, and it is difficult to see wherein the lower half are any worse than the lower half of American society. If they are, it is only because they have bettered the instruction of excellent and faithful teachers. Their laziness, so much talked about, is precisely what that of the Western farmer would be if overwhelmed by a horde of Chinese, who should pass laws that virtually compelled him to abandon his way of making money and adopt theirs, of which he knew nothing, and which would barely make him a living. If their possessions are gradually slipping from them and their lands passing into the stranger's hands, it is due to the laws and the heavy taxes we have forced upon them, much more than to either their own improvidence or want of thrift. And when more than half the Americans are going the same road, we might as well acknowledge that we do not know all about the best way to make a living in southern California, and that the old inhabitants did know at least something of that art; for it is certain they were nearly all wealthy and wanted nothing.

After their visit to the old Mission our friends were glad to sit down under Don Juan Forster's great front porch and look down the valley toward the sea, just as the flood tide of rosy mist began to flow in from the sinking sun, and the soft carpet of the high, smooth hills to run through all shades of purple, green and gold. The waves of light ran rippling over the rolling slopes of silvery-green wild oats; the emerald meadow in front was dotted with horses and cattle; the wild geese and brant in

clamorous mobs were marching in from the coast; the wild ducks in whizzing flocks scudded up and down the valley; here and there a snipe was pitching and squeaking aloft; the sandhill cranes, with dolorous "gr-r-rooo, gr-r-rooo," were floating across the blue zenith; the white pelican, the egret, or the swan, was winging its solemn way toward the laguna, and from the canyon came the clear "ohio, ohio," of the valley quail.

"It seems like an enchanted land, does it not?" said Laura. "I don't wonder so many people fall in love with California."

"You are now seeing it at its best. There are times when it is different from this," said Dona Juan, with a frankness that is too rare among the Californians, when any question about California comes up. "We experience here three kinds of winter. First, the 'good' winter, when there is just about rain enough, and that properly distributed; then vegetation is at its climax, crops are good and the sloughs and ponds have plenty of water, and geese and ducks, as well as other game, are plenty. Second, the 'medium' year, when there is not rain enough (or not properly distributed), to make much more than half a crop of grass and grain, but when there is still enough to feed all stock and cover most of the expenses of the settler. The first of these may be too wet for the very sick invalid, the second will be about right, and there is a third will suit him exactly, if he wants only clear, warm weather, and has no sympathy for a suffering land.

"But who with a sentient soul can behold the 'dry' or 'bad' winter and not feel sorrowful? Day after day and week after week the sun climbs the unclouded sky, sinks into his ocean bed of silver, carmine and gold, and flames next morning at the eastern gate with as smiling a face as that of a just-accepted lover. At long intervals, as if in mockery of our hopes, a very few raindrops patter on the roof. And once or twice there may be enough of a shower to tempt one to borrow an umbrella, but not long enough to make him yield to the temptation to keep it.

But January treads on the heels of February, and February joins March in the long procession of bright days, with a smiling face above, and sad and sickening faces below. Then yonder rolling hills of velvet green are brown and bare; the violets and the alfileria, called out by the first good rain, sprout, curl up and wither away, or seed out at an inch high; the earth yields no interest on the farmer's loan; the bee returns empty to his hive; the quail declines to mate; the hare retires like a monk to the cloisters of the rocks; and the goose returns disgusted to the north. The ewe deserts her new-born lamb, and the raven begins to feed on her before she lies down to die. The ox or the horse staggers to the spring and is unable to return; bloated and weary, the overworked buzzard sits around on the corral fence; and still nature keeps up her steady dress-parade of fine weather, and the sun smiles on, smiles on, as bright and soft as if bound on an errand of mercy instead of an errand of death."

As he finished this doleful description, Don Juan shrugged his shoulder, with a gesture of resignation; and then, recovering his wonted demeanor, he arose, and with a smile excused himself, to provide for the entertainment of his guests within.

"Many people are very much disappointed with California, and do not like it," said Belville, after his host's departure. "It has been so abundantly overpraised by some writers who, not content with dipping their quills into the rainbow, must tear up the whole brilliant arch by the roots and splash it over their pages, that thousands have come here hoping to enjoy the felicities of heaven without the preliminary of dying. And nobody who has taken his ideas from these hyper-diabolical books—hyperbolic I mean, but it's all the same in this case—can feel anything but a bitter disappointment when he comes to California. All this has produced a reaction, until it is now the fashion to be quite as unjust on the other side."

MUSIC AMONG MINERS.—"As I passed down Main street, I was attracted by a crowd of men standing in front of the tansorial saloon. They were listening to music and song coming from within—a guitar and accordion. The air played and song sung were very good, but soon a critic among the crowd arose and said: 'I can improve that by going home after my fiddle,' and off he went. A second, hearing the remark, said: 'By Jove! I will get my fute.' Another got his banjo, and another said: 'I will bring the snaredrum and triangle,' and in less than half an hour six musicians were on the ground. In ten minutes I was listening to a complete philharmonic band of good musicians performing together on their various instruments as one man. Is it not surprising what an amount of talent is hidden beneath the garments of our Pacific coast workmen?" This pleasant little incident took place in Tybo, so small a mining camp that the outside world hardly knows that it has an existence. The *Eureka Sentinel* agent there, C. B. Streibberger, reported it for the *Belmont Courier*.

CONCENTRATORS.—Before the introduction of the Frue concentrators in this district, only about forty per cent of the assay value of quartz could be obtained. Now rock yields fifty and sixty per cent by the Frue. There ought to be a fortune in the tailings that are being sent down to the lower country, if some process could be found that would work them up to eighty or ninety per cent.—*Nevada Transcript*.

Settling Tanks in Silver Mills.

The following "Notes on Settling Tanks in Silver Mills" were submitted at a recent meeting of the American Institute of Mining Engineers, by Albert Williams, of the United States Geological Society:

A large proportion of the work performed in wet-crushing silver mills is devoted to the handling and re-handling of pulp between the battery and the pans. There seems to be no generally applicable substitute for the settling-tanks, and in the present system of constructing mills the tanks involve an amount of labor which may be regarded as disproportionate and unnecessary, in view of the automatic improvements which have been introduced in other directions.

This difficulty has been met, however, by Boss's continuous process, in which the pulp flows directly from the mortars to the first of a series of constantly working overflow-pans. This method has been adopted at the Noondy mill, Bodie, California; the Harshaw, Arizona; the Sierra Grande, New Mexico; and the Prietas, Sonora. The continuous process, while giving excellent results with special ores, and under peculiar local conditions (such as a deficiency in water supply), is not, I believe, claimed to be available for all raw amalgamating mills, notwithstanding its well merited popularity for certain work. Some trouble has been experienced from the tendency to concentration in the pans, though this can be avoided by skillful manipulation. It has also the disadvantage inherent in combinations of distinct operations; it requires a very nice adjustment of the water supply to obtain full battery efficiency without running the pans too thin, though the latter defect is partially compensated for by the gradual thickening of the pulp as it proceeds through the series of pans. The objection is similar to that which holds in a parallel duplex process, that of combining roasting and smelting in a single furnace, where each operation is injuriously affected by the necessity of fitting it in with another and entirely different one.

In the prevailing type of wet-crushing silver mills, the battery sands, after settling, are manipulated in one of the three following ways: They are either shovelled into wheelbarrows or cars, and thus conveyed to the pans, or they are dumped in heaps upon the platform immediately back of the pans, from which they are again spaded into the pans; or, if taken from the row of tanks nearest the pans, they are sometimes thrown directly from the tanks into the latter by a single handling. Each of these methods may be applicable in a single mill, according to the arrangement of the tanks relatively to the pans. All involve hard work and the employment of many men. Thus of the force employed in six Comstock mills (the Brunswick, California, Mariposa, Morgan, Scorpion and Trench), which in 1880 numbered 215 men, no less than forty-nine were tankmen; and of the crews of two mills in Owyhee county, Idaho (the Ellmore and Jones & Adams), six were tankmen in a total of nineteen. The wages were \$4 per shift of ten and twelve hours. These eight examples show that twenty-four per cent of the labor in the mills named consisted in handling the tank pulp. The instances cited include all the data I have at command, and probably show a fair average of the practice in mills of the same type. Remembering the notable saving which has been effected in other details of modern amalgamating mills it appears that here is a possible opening for improvement.

The object of this paper is to throw out a hint which may invite discussion, and may suggest to the builders of the mills of the future a remedy for the existing clumsy, slow and expensive mode of handling tank pulp. Instead of the laborious shovelling of the heavy, tenacious pulp to higher levels from the tanks, why not utilize the always obliging force of gravitation? This is already done in passing the ore from the bins successfully through grizzlies, rock-breakers and ore feeders to the stamps, and in settling the pulp; and after leaving the pans the pulp flows downward to the settlers, and thence to the agitators and sluices. In all these stages the movement is steadily downward, and is effected by gravity. It is only when the settling tanks are reached that an interruption occurs. Suppose now, that instead of the ordinary tanks we introduce a series of hopper-shaped boxes provided with gates at the bottom, placing the pans six to eight feet below the usual level, and discharging the settling boxes into movable troughs leading to the charging holes of the pans. The position of these self-dumping tanks would be the same as that of the ordinary ones; the grade of sluices from the battery to the tanks would not be changed; and the arrangement of overflow gates would be identical. The tank capacity could also be kept the same while diminishing the area, for the capacity of the common tank is determined by the limit of depth from which a man can conveniently shovel—this depth ranging in present mills from twenty-four to forty inches, and seldom exceeding 30 inches. The proposed system would allow the compartments to be smaller in area because of their correspondingly greater depth. The gates at the bottom of the tanks could be actuated by levers extending above the pan floor. Perhaps the best arrangement would be to employ hinged bottoms surfaced with burlap, sheet-rubber, or

other packing. Any slight leakage would not be objectionable; for the water would be strained as it escaped, and all drippings would collect in a large fixed trough underneath the tanks, from which the water could be conducted to the slime ponds or used in diluting the pan and settler charges. The details of construction can be elaborated by any mill designer.

The plan of using gravity-discharging tanks is, I admit, open to certain objections. It demands steeper grades inside the mill, to allow room for a half floor beneath the tanks, and to give sufficient fall for the sluices from tanks to pans. The work of excavation for foundations would be increased, and the mortar beds would need somewhat heavier backing. On the other hand, the area occupied by the building could be slightly reduced. The expense would depend largely upon the natural grade of the site. For a twenty-stamp mill the addition to the first cost (given a favorable site) should not exceed \$1,000—an amount which could be saved in wages of tankmen in a three months' run.

Colorado Ores in Utah.

In the Montrose (Col.) *Messenger* of the 17th, we find the following: Mr. Knapp and Mr. Ferguson, two prominent smelting men of Salt Lake, were in Montrose Sunday morning on their return from Ouray. They had been investigating the chances for securing San Juan ore, for reduction in Utah, and have purchased several carloads to be used as a test. This is a step that is in the right direction for us. The smelters of Utah have been successful. Labor is cheap there, and the cost of reduction is, of course, low, and should these gentlemen succeed with their experiment, as they undoubtedly will, a splendid market will be opened up for our ores. Montrose being about midway between Denver and Salt Lake, we see no good reason why the Denver and Rio Grande road should not carry ore from here to Salt Lake for the same price it is now hauled to Denver for. If this is done, when the wagon road is completed from Ouray to Red Mountain, the ores of that famous camp can be shipped to Salt Lake for less money than to Denver by way of Silverton. Then if the Utah smelters can reduce the ores at a saving on Denver prices, all the ore of Red Mountain and the rich camps of Ouray and the San Miguel will find its market in Mormonland.

It may be urged that the Rio Grande interests in Colorado are such that they would prefer to work for Denver and Pueblo business as against Salt Lake, and consequently they may not give the latter place the same advantage on rates. We cannot see it in that light however. With 700 miles haul from Denver, and about 600 from Pueblo, to Salt Lake, on through traffic, it is much more to the interest of the narrow gauge to build up a great metropolis in Utah, than to help build up the Colorado smelting points. By building up a rich, prosperous and populous territory west of us, that company can look for an immense through traffic over their line.

Another item in favor of Salt Lake, is the fact that their coke comes from Colorado. The D. & R. G. would therefore have the hauling from Crested Buttes, a distance of nearly 500 miles, the very coke that would be used in reducing our ores after they reach the Salt Lake smelters. All this would tend very materially to increase the company's traffic, and we contend that by giving the western smelters good rates on San Juan ore, the railroad company will be pursuing a policy that can but result in building up an immense traffic for the road. Should the recent visit of Messrs. Knapp and Ferguson result in opening up a market in Utah for San Juan ore it will be a great thing for Southwestern Colorado.

NEW MILL AND NEW CONCENTRATOR.—Turnham & Co.'s new mill, at the North Bauer Tunnel mine, works very satisfactorily. Five stamps are kept busy upon a good quality of ore, and as soon as everything is ready the other five stamps will be started up. A Golden Gate sulphurets concentrator is being put in by G. W. Waitt, of Boston, who is on this coast for the purpose of introducing the machine, which is of recent invention, and which, it is claimed, will perform twice as much work as those of the Frue patent. The machine costs twice as much as the latter. This is the first one to be put up in this section, and the agent guarantees that if it fails to do as represented the owners of the mill need not purchase it. Should the working of the new concentrator prove unsatisfactory, Mr. Waitt will bear the expense of putting it up. The machinery at the above mill is driven by a Pelton wheel.—*Nevada Herald*.

THE AUBURN MINE.—It is reported that the Auburn mill and mine, at Dun Glenn, suspended operations yesterday. It is to be hoped that such is not the case, yet from what miners have been saying about the Auburn for a year or more, we fear the report is too true.—*Silver State*.

REPORTED BIG STRIKE.—By passengers on last night's train the report is brought that a very large chamber of exceedingly rich ore has been struck in the Christie Company's mine at Mineral Hill. No definite particulars could be had, but the story is that the find is of great importance.—*Eureka Sentinel*.

* From the "Rifle, Rod and Gun in California," by T. S. Van Dyke.

MECHANICAL PROGRESS.

A New Mode of Wire Manufacture.

A French invention for wire manufacture is described at length in a communication received from English patent solicitors. The present method of manufacture requires repeated passage of the metal first through the rolls for the purpose of reducing the ingot, and then through draw plates in order to further reduce the wire to the required diameter. The invention in question has for its object an improved arrangement of rotating ingot mold, whereby it is rendered possible to run out the metal directly in the form of wire of the required diameter or nearly so. This apparatus is composed of a vertical shaft supported at its lower extremity in a footstep bearing. The shaft carries a cast iron plate, provided at its outer edge with an annular channel, which is closed in or covered by a ring or annular cover forming the mold proper. For this purpose the ring is provided with a groove of suitable form for the reception of a molten metal, which is contained in a pocket or ladle, supported by an iron ring swivelling on trunnions or centres, and carrying a rod or arm, to the upper extremity of which is attached a cord, connected to and capable of being wound upon a pulley or drum on the vertical shaft. The lower part of this shaft is provided with a bevel wheel, geared with a corresponding wheel on a horizontal shaft, provided with fast and loose driving pulleys. The annular channel is supplied with water by a pipe, this water passes through a stop-cock, traverses footstep bearing, and is conducted along the centre of the vertical shaft, whence it flows through a radial pipe to the channel. The water escapes from the channel through another radial pipe, descends in the center of the hollow vertical shaft, and is discharged through channels formed in the footstep bearing, into a pipe provided for its reception. The metal run into the mold or annular groove is cooled by the circulation of the water and solidifies. The wire thus produced is lifted by a finger or point, and conducted away from the mold. The rotation of the shaft causes the cord attached to the arm on the ring supporting the ladle, to be wound upon the drum or pulley, thus tilting the ladle and causing it to deliver the molten metal in a regular and constant stream. The periphery of the drum or pulley is made of special form, determined by experience, with a view of causing the metal to flow with regularity. The framework of the apparatus is made of cast iron, and is provided with a trough or gutter for the reception of the water in case of leakage. The wire obtained by means of this apparatus requires to be passed once or twice through a draw plate. By suitably modifying the form of the revolving mold, the wires may be made with enlargements, swelling or other appendages of any suitable material.

Floors Weakened by Gas Pipes.

A short article in the *Building and Engineering Times*, on the subject of weakened floors, deals very intelligently with the harm that may be done in this direction by careless gas fitters. It is common enough, in cases where a pipe has to be led under flooring and across joists to serve a pendant, for the pipe to be taken straight across the center of the room, and the joists notched about an inch deep all the way. Workmen who do this never reflect on the harm they are doing to the floor, nor do they know that a notch cut out of the top of a joist will seriously weaken it. This at once becomes evident when it is known that the strength of a joist, which is a rectangular beam, is proportional to the depth squared. If, therefore, a groove one inch deep is cut across a seven-inch deal, the reduction of strength is not only one-seventh, but a great deal more, in the proportion of thirty-six to forty-nine, or a loss of rather more than one-quarter of the original strength of the beam. This somewhat startling result is due to the self-evident fact that the upper part of the joist is required to be solid, in order to resist compression, just as much as the lower portion must be capable of bearing tension; and to cut a notch in the top of it is equivalent to removing the substance along the whole depth of the joist, to the full depth of the groove. This observation only applies to cases where the notch is cut out of the center of the span, which is the common practice. There is much less objection to cutting joists close to the end, and thus allowing the pipe to be laid round the room to a point where it can be run to the center between two joists. Or, if this course cannot be followed, the pipe may safely be passed through a hole bored in the middle of the joists. If this is not feasible, the indispensable notch may be cut right down to the middle of the joist, and the pipe thus laid across the neutral line; the space above being afterward filled with a tight wedge which will safely transmit the compressive stress.

THE VALUE OF INVENTIONS.—It is generally supposed that small inventions have no value. But if we enquire more closely into the history of some of the "trifles" that have been invented, very different conclusions are arrived

at. Thus, it is stated that the stylographic pen yields to the proprietor of the patent no less than £20,000 annually. The same revenue is said to be derived from a patent for a pen for shading in various colors. The inventor of the gummed newspaper cover is now a rich man. The screw points at the ends of lead pencils have made the owner of the patent independent. The Abyssinian well is said to have yielded to the original inventor, Colonel Green, no less than £600,000. The inventor of the roller-skates is reported to have acquired a fortune of £200,000. Even ordinary toys for instance, the returning ball, with India rubber coating, and several other amusements for children—have returned from £10,000 to £15,000. The toy called the "Crier" brought the inventor within nine months a sum of £30,000. Although these few instances by no means prove that all small inventions must yield such profits, it may, nevertheless, be said that many are lost to the inventor from want of energy and perseverance, while another person, who will take the matter up later, will make a fortune by them.

IMPROVEMENT IN HOT-AIR ENGINES.—The *Manufacturers' Gazette*, in speaking of hot-air engines, says: "In an improved form of hot-air engines now coming into use, the action is such as to overcome almost all the difficulties encountered under the ordinary system. After the fire is made, the retort becomes heated to a dull red heat, which rise of temperature expands the small amount of air inside the piston, being by this means forced in the air cylinder downward. After this expanded air has done duty, the displacer, which is actuated from a crank, forces the air which has been condensed against the cold sides of the top part of the cylinder back to the hot end of the retort. As the piston performs its stroke, due to the expanded air in the cylinder, a small air valve is kept closed by the pressure; but as the piston makes the return stroke, a small valve on the top of the cylinder opens for a sufficient length of time to permit air to enter the cylinder, to replace any which has escaped through defect in packing. It is therefore not only automatic in receiving the proper supply of air for expansion, but is also automatic in its lubrication, for whenever this down stroke is made, a small amount of oil is drawn into the cylinder for lubricating the metallic piston—a great advantage in hot-air engines."

MALLEABLE NICKEL.—Pure nickel, after melting and casting, generally holds a greater or less quantity of oxygen in solution, and the metal is brittle. To hinder the injurious effects of the oxygen, it is necessary to incorporate in the melted nickel some substance which has a strong affinity for oxygen and also for the nickel itself. J. Garnier finds that phosphorus serves both of these purposes very satisfactorily, producing effects analogous to those of carbon in iron. If the phosphorus does not exceed three tenths of one per cent the nickel is soft and very malleable; above this quantity the hardness increases at the expense of the malleability. Phosphorized nickel, when alloyed with copper, zinc or iron, gives results which are far superior to those that are obtained from the same nickel when not phosphorized. By means of the phosphorus, Garnier has been able to alloy nickel and iron in all proportions, and always to obtain soft and malleable products. The contradictions of illustrious chemists are thus explained, some saying that such alloys were brittle, others that they were malleable; the latter had alloyed the nickel to phosphorized iron.—*Comptes Rendus*.

ELECTRICITY AS A RAILWAY MOTOR.—Mr. Edison is said to claim that, by means of a central rail, electricity can be used as a motor on railways so as to effect a saving of thirty-three per cent in present cost of coal for steam locomotives. He admits, however, that electricity is not likely to be generally adopted for heavy freight trains or through passenger trains, but believes that electrical motors will be invaluable for street cars, elevated railways and other short lines. An example of their adaptation to these purposes will be seen on the elevated electrical railway at the railway exposition. At present it is admitted that electricity as a motive power is not as economical as steam for operating railways, but it is not impossible that in the future much greater economy may be introduced.

CAST IRON CHILLED TOOLS.—At a recent meeting of the Institution of Mechanical Engineers, in England, Mr. Fielding exhibited some cast iron chilled tools, and said that with chilled tools—the cost of which he showed to be merely nominal—he was able to turn cast and wrought iron and gun metal at from 50 to 100 per cent higher speed than with tools made from steel. He expressed surprise that such tools had not come into more general use.

DON'T OVERDRIVE YOUR MACHINERY.—The policy of driving our machinery is a losing one. When normal speed is on, and the machinery is running, all is well, but the moment the speed is increased beyond the natural bearing capacity, something must give way. It may not be at once, and the unnatural speeding may go on very well for a term, but the machine is wearing away faster than it should, and some of these days the man who runs it will be forcibly reminded of the old deacon's "one-hoss shay."

SCIENTIFIC PROGRESS.

Telpheage.

This new term is applied to a mode which has been devised by Prof. Fleeming Jenkin, of Edinburgh, for the transmission of vehicles containing goods to a distance, by means of an electric current, not connected with the vehicles themselves. The Professor's idea is to employ strained metal cables, which will serve both to sustain the load and convey the electric current. The frames or trucks supporting the load run along the cable on wheels, and the cars or loads are suspended below them from the axles of the wheels. In the simplest arrangement of the line there is a break of continuity at each post supporting it, and the sections of cable are themselves insulated from each other and the earth. They are, however, capable of being connected by movable coupling pieces, actuated by the train, so that all the sections receive the exciting current and form part of the general circuit. The current is supplied to the line by a stationary dynamo-electric machine, and since the line is elevated from the ground on insulating standards, the same dynamo will supply a considerable length of line, as the leakage need not be excessive if proper precautions are taken. Mr. Edison has adopted the plan of dividing the whole line into short sections of a few miles, with stations and feeding dynamos at each. Dr. Siemens favors the use of an insulated conductor supported beside the line, and giving current to the motor on the train by means of a running connection pulled by the train. Prof. Ayton and Perry have sought to overcome the leakage difficulty by making the line in very short sections, each of which is put in circuit with the dynamo in turn as the train progresses, by an automatic action of the train itself. In this way there is only one section electrified at a time—namely, that over which the train is running—and the leakage on the whole line is consequently very small.

The loads or cars on the telpheage line are connected together in trains, and the length of a train is nearly the length of a section of the cable or conductor. On passing either of the movable coupling pieces between two sections the train throws it out of action, disconnecting the two sections at that point, but the circuit between these sections is maintained through the wheels of the train itself and a conductor on the train. In circuit with this conductor is a dynamo-electric motor, which is actuated by the current, and propels the train by driving the wheels. The train is provided with a governor, which acts directly to check the train if the speed becomes excessive by short circuiting the electro-motor, or otherwise bringing electric brakes into operation. To further insure that one train shall not overtake another, Prof. Jenkin provides an automatic telegraphic communication along the line, and the trains, in passing, close and open the telegraphic circuits. It will be seen from the above description that the control of the trains is completely automatic and independent of the train officials.

New and Remarkable Chemical Experiments.

The liquefaction of oxygen gas and nitrogen, the freezing of alcohol and sulphide of carbon, are the latest achievements of chemical science. This news comes to us from the laboratory of M. Wroblewski, in Cracow, Poland, who has given some interesting particulars in a dispatch to M. Debray, published lately in *Comptes Rendus*. By the use of liquefied ethylene, M. Wroblewski and K. Olszewski obtained the remarkably low temperature of 136° C., equal to 212.8° F. Oxygen gas subjected to about this temperature, and compressed under a pressure of about 25 atmospheres or 375 pounds to the square inch, was readily liquefied in glass tubes, and formed a colorless and transparent liquid, very mobile, and resembling carbonic acid.

Nitrogen was also liquefied, forming a colorless liquid. Alcohol was solidified at 130.5° C., or 202.9° F., forming a white body. Sulphide of carbon froze at about 116° C., or 176.8° F.

These are certainly very interesting and remarkable experiments. Air contains by weight, approximately, 23 parts of oxygen and 77 parts nitrogen. It is common to compress it to a far greater degree than above mentioned. For motive power, in driving compressed air locomotives, a compression of the air to 1,000 pounds to the square inch is in some cases employed. The difficulty heretofore experienced in the liquefaction of oxygen and nitrogen has been to obtain a sufficiently low temperature in conjunction with compression. This obstacle now appears to be removed, and a variety of new and valuable observations concerning the nature of gaseous substances may be expected.

THE CHEMICAL EFFECT OF SUNLIGHT ON PLANTS.—Dr. Hermann Vogel, in his treatise on "The Chemistry of Light and Photography," points out the chemical effect of sunlight on plants, and especially the modified growth of plants owing to differences in the intensity of light, stating that these variations in the chemical intensity of light are very important to the life of plants. The green leaves of plants imbale carbonic acid and exhale oxygen under the influence of light, but this breathing process does

not take place in the dark. Without light, plants develop only sickly blossoms, like the well known white germs of potatoes kept in cellars. The necessity of light for the life of plants is also seen in the effort made by plants kept in darkened rooms to reach the apertures which admit light, growing, as it were, toward them. The plant, therefore, develops with an energy proportioned to the intensity of the light, and the greater fruitfulness of the tropics is to be ascribed not only to the higher temperature, but also to the greater chemical intensity of the sunlight. Recent observations have established that the red and yellow rays, and not the blue and violet, produce the greatest chemical effect on the leaves of plants.

HYDRAULIC SILICA.—If a solution of potassium or sodium silicate (water glass) is decomposed by an acid, gelatinous silicic acid separates. If this be dried at a red heat, and the operation repeated until the alkaline salts are entirely removed, a pure silicic oxide (silica) is obtained that is insoluble in acids. Landrin says it is the source of the real hardening of hydraulic mortar.

In certain cases the aluminate of lime is a help to the setting of the cement, somewhat as gypsum would be, for, notwithstanding its slow solubility, it renders the combination of the hydraulic substances easier at the first immersion and prevents the rapid entrance of water into the mass of the mortar, which is favorable to the slow and gradual union of the lime with the hydraulic silica. It is a fact, for instance, that the lime from Theil, which contains none of the aluminate, cannot be used for hydraulic constructions in the ocean, because it crumbles before it sets, while it is proved very valuable for use in the Mediterranean sea.—*Compt. Rend.*

VEGETABLE PARASITISM IN FISHES appears, from recent observations made by Messrs. Olivier and Richet, to be so constant that it may be regarded as normal. These gentlemen examined about 150 fishes taken in the Channel and the Mediterranean, and in all of them they found in the peritoneal liquid, in the lymph, in the blood, and so in all the tissues, microbes more or less numerous, having all the characters of land microbes, and being capable of similar reproduction. These organisms were mostly the bacterium called *Bacillus*. The authors cultivated these microbes successfully. They also repeatedly made an experiment which consisted in putting a whole fish or part of it in paraffine melted at 120° or 140°. After solidification, the paraffine was coated with several layers of collodion and Canada balsam. The tissues thus guarded from atmospheric germs all showed, after a few weeks, an extreme development of microbes which were not those of putrefaction. The authors propose to investigate the mode of penetration of these parasites and their influence on the vital functions.

THE TRANSMISSION OF SOUND THROUGH ROCK.—Some very interesting observations have been made in the course of mining work in the Hartz mountains, Germany, on the distance through which sounds are transmitted in rock; the latest facts relating to the subject being recorded by Herr F. Schell, of Grund. In a horizontal direction, the firing of shots at the face of a cross-cut has been heard in a cross-cut driven toward it, the face of which was 447 feet distant from it. Until recently, however, no occasion has presented itself to observe how far sound was transmitted in a vertical direction. A level was driven on a vein at a depth of 538 feet below the surface, and happened to strike 187 feet distant, in a horizontal direction, below the stamp mill dropping stamps weighing 300 pounds. The dropping of the stamps on the surface could be distinctly heard in the heading below, which in a direct line, the hypothenuse of a right angle triangle, was separated by 471 feet of rock.

SELENIUM AS A REGULATOR OF HEAT.—According to the *Comptes Rendus*, Mr. P. Germain proposes to use the various degrees of resistance which selenium opposes to the passage of electricity at different temperatures and under different rays of the spectrum, to the regulation of the temperature in muffle for enameling painted glass or porcelain. He uses a thermo-electric battery of thirty elements, which receives the heat directly from the muffle. The opposite pole is connected with the wall of a porous vessel, full of water, which maintains a sensibly constant temperature. The thermo-electric current increases in potential proportionally to the elevation of temperature in the muffle. The selenium which is brought into circuit remains comparatively unaffected until the muffle has reached the proper luminous temperature, when it allows the current to pass and to give a signal by means of a bell.

WILL GAS PASS THROUGH STONE?—Prof. Doremus has shown this to be the case in some experiments made not long ago. A block of brown sand stone, twelve by fifteen inches long and four or five inches thick was used. A pipe was clamped on to the stone by means of iron plates, and this pipe connected by means of flexible tubes with the gas pipes. The remainder of the stone was painted over several thicknesses with varnish. Opposite to the point where the gas was applied there was another pipe for the gas to escape from. In a few moments a lighted paper applied to it caused a flame to appear, showing that the gas had passed through the stone.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

BUNKER HILL.—Anador *Leader*, June 9: The second clean-up at the Bunker Hill mill since the resumption of work was made Wednesday of last week. The run was for about 25 days with 10 stamps, and the yield was about \$5,000 in bullion, besides sulphurets, valued at \$1,000. This is considered a very satisfactory result. The employees were paid off last Tuesday, and the second installment on the back indebtedness was paid promptly according to agreement.

MISCELLANEOUS.—The clean-up of Hadley & Vair's gravel claim at Bunker Hill about a fortnight

MISCELLANEOUS.—The clean-up of Hadley & Vair's gravel claim at Posey Hill above Volcano was finished last Friday, and resulted in enriching the lucky owners to the tune of \$6,000—a big yield. The Kelly mill is cleaning up on Morgan's rock, with prospects of a good yield.

FROM SUTTER CREEK.—Cor. Amador Ledger, June 9: The Amador canal is still giving trouble. Two breaks have occurred since my last writing, which involved considerable time and expense to repair.

ANOTHER SUIT COMMENCED.—Another suit has been commenced over the Mammoth mine. This time Mr. Fenton is the plaintiff. He did some work on the claim 17 or 18 years ago. The suit has been started in the United States Court in San Francisco, and the demand is for 600 feet of the north end of the claim, which includes the bonanza. The complaint alleges fraud in the securing of the patent. That is always the way. When a man strikes a good thing, no matter how straight-forward and honorably he acted in obtaining possession and title, half a dozen claimants rise up and conjure up some ground for litigation and worryment. The new suit will not be likely to interfere with the prosecution of work.

COAL.—*Amador Dispatch*, June 9: We were shown a large chunk of fine looking coal the other day, taken from the mine, near Lancha Plana, owned by Messrs. Murray and Waddell. It appears to be greatly superior in quality to the lone coal, and can be worked to advantage as soon as the means of transportation becomes more convenient. The vein is about seven feet in thickness.

Calaveras.

From Mr. McNevin's—*Cor. Min. Echo*, June 9; Halted a mile west of town the little one-stamper, of great capacity, lifts and drops its mighty arm night and day, with the precision of clockwork. A visit to this little mill is sure to please one. Its simpleness is the one great feature, and one is convinced that its 130 drops a minute will do the work that is claimed for it. The ore from the mine—O. K.—on which it is running, is of good quality, and the mine looking finely. Messrs. Knowlton, Soublett & Co., have a good property, and are deserving of it. A few miles north of town, on the Washington, all is activity. The carpenters are busily engaged in erecting a fine residence for the Sup't. Mr. McNevin, and other necessary buildings will follow in quick succession. Work has been retarded somewhat on account of the difficulty of getting lumber on the ground. The new shaft is being driven with all the speed that experienced miners can accomplish in eight hours.

Mining Share Market.

Mining stocks have not acted very encouragingly to dealers this week, as our tables show. The Comstock have not held up, as was expected, notwithstanding no less an authority than Mr. Flood speaks favorably of the situation there. He believes the Comstock is to-day the best place in the world in which to find a mine. He has not lost control of the north end mines, neither does he intend to. He says there is nothing to fear from the water. Mr. Flood expects Mackay home in a few weeks, when he and Mackay will visit Virginia together and make a thorough inspection of the mines. He regards the present situation as very hopeful, and says deep mining is no obstacle to success, though its pursuit requires courage, and economy will have to be practiced in order to produce the best results. Mr. Flood is considering the practicability of introducing the electric light into the mines. The Satro tunnel, he says, is the salvation of the Comstock. He thinks Mr. Fair either misrepresented, or that he was laboring under some kind of hallucination, when he said what he did about the Comstock in New York.

The following are the financial balances of the various mining companies on June 1st: Cash on hand Alta, \$28,875.00; Albion Con., \$54.93; Ar-genta, \$3,519.58; Belcher, \$26,750.36; Benton Con., \$6,488.66; Bechtel, \$241.96; Bodie Con., \$41,334.99; Bulwer, \$12,229.97; California, \$14,809.93; Con. Virginia, \$35,074.34; Chollar, \$38,984.12; Crown Point, \$21,161.27; Challenge Con., \$5,160.23; Con. Imperial, \$2,276.87; Day, \$5,159.83; Gould and Curry, \$12,349.04; Hale and Norcross, \$17,087.61; Jackson, \$2,279.87; Lady Washington, \$5.83; Mono, \$3,044.85; Mexican, \$31,357.64; Northern Belle, \$93,740.65; Ophir, \$25,960.73; Occidental, \$6,629.00; Potosi, \$4,873.05; Scorpion, \$6,231.57; Savage, \$22,735.33; Standard, \$98,754.72; Sierra Nevada, \$59,104.60; Silver Hill, \$2,547.14; Utah, \$750.50. Indebtedness Best and Belcher, \$7,802.41; Grand Prize, \$11,879.04; Utah, \$3,448.23.

WATER-GAS FUEL FOR STEAMSHIPS.—A test is about to be made in England of the use of water-gas as fuel for steamships. The Mauritius steamship line has built a steamship called the *Heron*, of 1,000 tons burden, and provided it with the apparatus invented by Dr. C. Holland for making water-gas. Dr. Holland's process has been tested on the Long Island and Erie railroads; but this is the first time that it, or any similar process, has been applied to a steamship. The *Heron* is to ply between London and the islands of Mauritius and Madagascar, and it is expected that she will start on her trial trip on May 10th. She has been fitted out with six furnaces precisely like those placed by Dr. Holland in the experimental locomotive named after him on the Erie road.

Isthmus Railroad.—Active work has been commenced on the Tehantepec railroad. The steel rails are already on the ground, together with six engines and a large number of cars. Senor Sanchez, President of the company, is now in the United States ostensibly to rest a while from his arduous labors, but in reality he has been commissioned by the Mexican government to negotiate a small loan for the purpose of completing the isthmus railroad. As this line belongs exclusively to the government, and prompt payment will be guaranteed, the necessary funds will, no doubt, be readily obtained in St. Louis or New York.

COAL.—*Amador Dispatch*, June 9: We were shown a large chunk of fine looking coal the other day, taken from the mine, near Lancha Plana, owned by Messrs. Murray and Waddell. It appears to be greatly superior in quality to the lone coal, and can be worked to advantage as soon as the means of transportation becomes more convenient. The vein is about seven feet in thickness.

Calaveras.
FROM MURPHY'S.—Cor. *Alt. Echo*, June 9: Half a mile west of town the little one-stamper, of great capacity, lifts and drops its mighty arm night and day, with the precision of clockwork. A visit to this little mill is sure to please one. Its simplicity is the one great feature, and one is convinced that its 130 drops a minute will do the work that is claimed for it. The ore from the mine—O. K.—on which it is running, is of good quality, and the mine looking finely. Messrs. Knowlton, Soublett & Co., have a good property, and they are deservng of it. A few miles north of town, on the Washington, all is activity. Carpenters are busily engaged in erecting a fine residence for the Sup't. Mr. McNevin, and other necessary buildings will follow in quick succession. Work has been retarded somewhat on account of the difficulty of getting lumber on the ground. The new shaft is being driven with all the speed that experienced miners can accomplish in eight hours.

El Dorado.—Georgetown *Gazette*, June 9. Should the new Enreka ledge continue to hold its present thickness in depth and retain its richness, it will be one of the best dividend paying mines in the State. The lode is more than 10 ft wide, and prospects well in free gold throughout, averaging, so far as we can judge, about \$10 per ton in free gold; but Mr. Cheek who is opening the lode, thinks it will average fully \$15. The quartz is now showing quite a per cent of fine looking sulphurets, which may be rich in gold for all we know.

Fresno.
A VALUABLE MINE.—*Fresno Republican*, June 9: The Albion mine, situated in Fine Gold mining district, is rapidly coming to the front as one of the most valuable mines in the county. On May 26th, \$1,214.10 was obtained from 11 tons of rock, or at the rate of over \$110 per ton. They are now working at a depth of 50 ft from the surface, the ledge widening and getting richer as they descend. They have abundance of water for hoisting purposes. Wm. Robertson and Jessie Morrow, of this city, are owners.

Mono.—TEMPORARILY CLOSED DUE TO.—*Bodie Free Press*, June 6: The Bodie Tunnel mill has closed down temporarily. Supt. Thomas Buckley states that of late the mill has been working low grade ore, and it is thought advisable to open up some rich veins known to exist west of the present workings. While this dead work is progressing the mill will remain closed.

Nevada. *To be worked.*—Nevada. *Transcript:* The American claim, owned by the Citizens Bank of this city, is situated on the south bank of Deer creek, four miles east of town. It embraces 120 acres, and is supposed to include the outlet of the rich Quaker hill channel, from which much gold has been taken at various places. The ground in the American location has never been worked at all as yet, but negotiations now pending are likely to result in it being opened up during the present season. It is favorably situated for hydraulicking, and perhaps can be drifted to advantage. The new ditch of the South Yuba Co. runs by it, and a fall of 300 ft could be obtained.

THE NORTH BANNER.—Nevada Transcript, June 9: Five stamps of the new 10-stamp mill at the North Banner Tunnel mine (Ternan & Co.'s) are now pounding away steadily on good ore, the machinery doing its work well. G. W. Waitt, from Boston, is putting into the mill a sulphuret concentrator called the Golden Gate, which is a very recent invention.

Placer.
A PENRYN MINE.—Placer *Argus*, June 6: The Chicago and Pacific M. and M. Co., is the full name and title of an incorporated company who are operating a mine one mile east of Penryn. The works

comprise a 200-ft shaft, with tunnels extending north and south from the 100-ft and 200-ft levels, together with hoisting apparatus and a 10-stamp quartz-mill worked by steam. At the 100-ft level the northern tunnel is 125-ft long, and the southern, 90-ft while at the bottom of the shaft both tunnels are 180 ft in length. Not much has been done lately, owing to certain improvements, such as the putting in of two Frue concentrators; but in a short time everything will be ready for a good start, and 20 to 25 men will be employed at the mine and mill. As present there are only six. We are informed that a good body of ore is in sight, and that the prospects for the early development of a first-class property are excellent. The company is made up chiefly of Chicago capitalists—whence doubtless the name. Francis W. Pike is the name of the new superintendent, and W. H. Oates is the foreman. The company run their own boarding-house.

Plumas.

COPPER.—Greenville *Bulletin*, June 6: During the past two or three years the Engle Brothers have been prospecting for copper on the mountain east of North Arm. Last year they found a ledge cropping out at an elevation of about 1,600 ft above the stream; on this they sunk 40 ft to test the vein, and the result being satisfactory they then started a tunnel that would cut it at an additional depth of 100 ft. This tunnel has now reached the ledge which is found to be of great width, probably 40 ft; the ore is estimated to contain as high as 40% of copper. On the surface the ledge crops out for a long distance. The father of the Engle Brothers is an old German miner, familiar with the copper mines at Germany; he is now with his sons and is confident that mines of great value can be found on this claim.

OPHIR CO.—This claim is east of the Indian Valley mine and contains two ledges, named respectively the Ophir and Primrose; these run parallel to each other, and are about 100 ft. apart. No. 1, Hall is the sole owner. North and south the claim is bounded by patented ground. In sinking a distance of only ten ft. in the Primrose the ledge opened out to over three times the initial width; prospects on the Ophir ledge are also very encouraging. Mr. Hall shows quartz taken from this ledge that is quite rich; it is not "spotted," but has the gold well distributed through the mass, and has such general characteristics as warrants the belief that there is a large body of it.

WOLF CREEK.—The ledge discovered by McIntyre and Deal is 25 ft wide; the ore is richer than any seen in that locality for a long time. An amicable arrangement has been made between all the parties concerned so that no vexatious delays will prevent the steady working of the mine. A greater activity than ever is among the probabilities for that place.

San Bernardino.
BEST.—*Cadco Print:* The ore body consists of two veins of black metal mixed with iron silver and red chlorides. These veins are about eight feet apart run parallel and dip at an angle of forty-five degrees to the southwest. The upper and most convenient one to follow has been stripped by an inclined shaft to the depth of 20 feet, where it changes its course and apparently goes straight down. This fact was noted with much satisfaction by the owners, who are fully persuaded that the two veins combine at no great depth, forming a lead from which ore can be extracted with great rapidity. Over five tons of ore, expected to work \$700 or \$800 per ton, have been taken out, and will soon be milled. Work will then be suspended during the heated term.

BISMARCK. This mine, like its neighbor, the Humburg, is astonishing all by the richness of its deposits. Mr. Godfrey reports another rich strike near the east line of the claim.

OCCIDENTAL. Messrs. G. N. Jackson, foreman of the Oriental mine, and Andy Hunter, have leased the western portion of this mine, next to the Humburg. Two men are at work taking out ore similar to that in the latter mine, and more men will be added as prospects justify.

HUMBURG. This phenomenal mine is still holding its own. There is 800 tons of ore on the dump, mined by four men in less than four days.

EXCHEQUER. This is decidedly a rich mine. The developments of the last few days have removed all doubts of its permanent value.

GRANITE DISTRICT. *Calico Print:* Several days ago, Messrs. Joiner & Morrow called at our office. They had just arrived from Granite district, where they have been prospecting for some time, and have taken up a dozen or more copper claims. They bring in some very flattering reports concerning the prospects of that camp. If one-half of what is supposed to exist there in the matter of copper is ever taken from the mines, it will be immense. We were shown

some fine specimens of copper containing a small percentage of galena, which assays fifty or sixty per cent of copper. There are a few ledges that are said to be forty or fifty feet in width, and many six feet in width. The specimens shown us came from some new locations recently made this side of Granite wells. They are claimed to be very favorably located, and are six or eight miles nearer the railroad than the older locations. The claims have only been partially prospected, but enough to cause the owners to be highly elated over what they have discovered. They intend to do more work on the claims as soon as possible, and put them in a condition to meet with a ready sale. The lowest assay made was eleven per cent, and the highest ninety. It may take some time to put the mines out there in a condition to command good prices, but the time is coming when they will be opened and be a source of great wealth to the county.

Sierra.
NUGGET.—*Mt. Messenger*, June 9: A nugget, weighing 12 ounces, two of which is quartz, worth about \$200, was picked up in the ground sluice, last week, at Mowry and Eggleston's diggings, Craycroft hill. The Extension Co. took out 88 ounces and 6 pwt. of gold, last week. An old miner remarked that it was the handsomest lot of gold dust he ever saw. It brings \$18.60 per ounce before melting. Its true gold value at the mint is \$19.72.

Shasta.
FROM FRENCH GULCH.—Cor. Shasta *Courier*, June 9: The deal in precious metal increases; the mines grow better. Jim Blakemore, (Old Red as the boys used to call him in early days, when he was really a boy) has found a big prospect in Jennings's, a branch of Eastman's gulch, many think it is the father of all the lodes in the Deadwood locality. It

is, I believe, on the opposite side of the ridge from Deadwood, and is a ledge from 15 to 20 inches in width, though they are competent judges, think the quartz is very good, setting the average value \$200 per ton, others think it will give returns far in advance of those figures. Ten thousand dollars was offered for one mine in the Deadwood district, and \$15,000 for another and been refused by the owners, who know what they are worth. Frank & McDonald Bros. had another shovelled up last week of between 23 and 24 tons and got a \$5,000 date, and there is no stock for sale there. L. Hootaling and Mr. Eaton, of Redding are mining in the East Fork district which contains huge possibilities.

Tetbury.

BUCKLEY HYDRAULIC.—*Or. County Journal*, June 9: Mr. Yale has leased the mine for one year, and assisted by nine faithful workmen, he is doing good work. He has recently tunneled through the bed-rock some 10 ft upon the present bed-rock drift, giving him a greater fall for carrying off debris. This tunnel is some 50 ft long, and at the time of my visit, not quite completed. Going down a shaft about 12 ft, supplied with candles, we entered the tunnel and passed its entire length. This tunnel connects with another longer one at the base of the shaft. Some \$500,000 have been expended on this mine and its equipments, and present prospect of its becoming a paying mine are better than they have heretofore been. Only Phillips, at Lewiston, has recently struck a quartz lead that prospectively promises well.

NEVADA.

Washoe District.

CALIFORNIA. *Enterprise*, June 9: C. and V. winze sunk and timbered 10 ft. South drift on the 2,900 level advanced and timbered 13 ft.

UNION CON.—On the 3,000 level are cutting out a station in the joint Sierra Nevada winze.

OPHIR.—Are repairing the old Central tunnel, and putting new ladders in the main incline. Are extracting ore from the croppings. Have started the pumping engine. There have been 523 tons extracted and sent to the mills.

SILVER MOUNTAIN.—On the 3,000 level are cutting out a station in the joint Union Con. winze.

CHOTLAR.—During the seven days ending this date 14 ft were added to the length of crosscut No. 3, on the 2,600 level, making the total length 202 ft. On Monday, the 4th, work was suspended in the face of this drift, owing to the proximity of the west country. In the evening of the 4th, a drift was started southwest, at a point 12 ft west of the main lateral in crosscut No. 3. This drift was carried forward 22 ft. The material passed through was quartz, porphyry and clay.

YELLOW JACKIE. At the Winters shaft we are extracting and shipping about 150 tons of ore per day. The air in the north drift on the second level got so foul that we have been obliged to place a blower and air pipe to renew the same. Are making good progress in the work of reopening the fourth level, and have cleaned out and retimbered the west drift 125 ft from the station.

Belmont District.

IMPROVING.—*Courier*. The Belmont mine is improving at every point as the work of development advances. Very rich ore was encountered during the present week in the Knight ground, and also in the south tunnel. In the Moore & Martin ground, and at the north end, good ore is also encountered daily.

Bernice District.

WORK PROGRESSING.—*Silver State*, June 7: Bernice district is coming to the front as a mining camp. W. Gilbert, just in from the mines, reports the prospects as being first-class. There are 25 or 30 miners at work on the mines, several of which are yielding ore. The Silver Ridge and Wild Goose are producing rich ore, and Mr. Gilbert is here making arrangements to get teams to haul the "shipping" ore from those mines to the railroad, either to be worked here or sent to Salt Lake City. They have 50 or 60 tons at these mines ready for shipment, and any quantity of it in sight. Wallace Goodell is at work on the Golden Crown mine, and has several hundred tons of ore on the dump. A roasting mill is being erected by G. W. Botwell, to work the ore from this mine, and the mill is expected to be completed about the 1st of July. There are a great many other mining claims in the district, on which more or less prospecting has been done. Some of these are large-sized veins, which yield good milling ore that will not pay for shipment. It is expected that the new mill will reduce those ores at reasonable prices, and thus encourage the development of the district.

Bullion District.

A LIVELY CAMP.—*Silver State*, June 6: John E. Gilligan, of Elko, who has just returned home from Bullion Mining district, which lies near Cortez and some 25 miles south of Bismarck, gives the *Independent* a glowing account of the mines, the richness of the ore and the general prospects of the camp. He says a whirlwind of excitement regarding these mines is rushing through Lander county and spreading like a prairie fire. The denizens of Lewis are just packing their goods—and houses, too—on jacks, and navigating bags and baggage to the camp. Three mines have been sold to outside capitalists, and two other bonded within the past two weeks, and three newly incorporated companies are now shipping out to Bismarck with which to begin operations. About 200 prospectors are in the district. The live-stamp chloride mill—only one in the district—is turning out 300 pounds of bullion per week, and they are now grading for the erection of an improved ten-stamp mill immediately. Other mills will also quickly follow, for there is plenty of ore to keep them steadily employed. Mr. Gilligan may possibly be over-sanguine, but in speaking of those now going into camp he remarks: "They have got natch the best of those who rushed out to Arizona, Wood River and other foreign excitements, for before the latter can get back, a town lot in the city of Bullion will be in itself a bonanza."

Columbus District.

MOUNT DIABLO.—*True Vision*, June 9: The intermediate drifts below the third level, and west of winze No. 1, is giving a small amount of \$75 ore. The ledge in the slope east of winze No. 2, is in two and one-half feet in width, and a says \$65 per

ton. The bopes near the head of winze No. 2, both above and below the third level, are looking well and yielding considerable \$80 quartz. A small amount of \$100 ore is being taken from above and below the third level, near winze No. 1. The intermediate drift, nearly above winze No. 1, between the second and third levels, is producing some \$200 ore from a 10-inch ledge. The slope above the west drift from the Callison winze is looking well and yielding considerable ore. The western end of this slope does not look so well, but the center and eastern end both show improvement. The ledge averages two and one-half feet in width, the ore averaging \$75 per ton in grade. The east intermediate drift between the first and second levels, is giving some \$100 chloride. A shipment of bullion amounting to \$5,807.42 was made May 31st, and one of \$6,874.61 on June 4th. The total shipments for May were valued at \$61,822.74.

Eureka District.

GOOD PROSPECTS. *Sentinel*, June 6: There has been a very perceptible brightening up among the growlers in the last few days. The names are brightening up, and that cause it. The fact is that the mining outlook was never better in Eureka county than it is to-day. We don't mean by this that more ore is being taken out or reduced, but we do mean that more mines are being worked and more custom ore is being reduced than ever before in the history of the camp. There is a large amount of money being turned loose in the camp, too. Where it goes to, the All-Seeing Eye alone can discern. There is a rat hole somewhere that nobody can locate. Nobody will admit that he is getting any of the here, and we'll swear that if the sack has struck anywhere in our immediate neighborhood we don't know it. The producing mines of the county during the first three months of the year, exclusive of Albion, these alone, paid out over \$150,000 for expenses. The Assessor's books show this. This is substantial and a thing of the present. The future is bright. All along the line we hear good news. At the Geddie & Bertrand, Supt. Clarke thinks they have a bigger body of ore than was ever uncovered in the mine before; the news of an old time bonanza is brought up from Mineral Hill, Safford makes a showing that warrants the most sanguine expectations; we do not agree with the *Express* in valuing the Onondaga at \$100,000, but every body that has seen it says that it is a big mine; Eureka Tunnel is showing up better and better all the time; the Albion is looking better to-day than at any time since it got into trouble; for the last six weeks almost every day we have had to chronicle the discovery of ore in some one of a thousand little mines; the Ruby Dunderberg looks as though it was about to be itself again; it had 10 tons of ore at the Richmond for sampling yesterday; and yesterday the Alexandria mine showed up a three-ft body of \$70 quartz ore in the winze. All we want now to make Rome howl is to make all these things stick and to strike ore in the drift from the Eureka Con. new shaft.

Mammoth District.

THE FLYING. *Grantsville bonanza*, June 4: H. Harries returned from an extended trip through Mammoth Mining district on Monday. He speaks in glowing terms of the mines he saw at Ellsworth and Marble Falls and says that he had no idea that there was so much ore exposed. He is confident that he can successfully locate the ores and leave a good margin of profit both for himself and the owners of the mines.

Silver Point District.

ORE.—*Belmont Courier*: From Joseph Enghouse we learn that Frank Carrio is about to ship a number of tons of first-class ore to the Jefferson mill for reduction. He also informs us that the mine owned by Postmaster Woodson Garrard, James Wilson and James Bryson is being worked constantly, and they are striking very good ore. The work of development is also being prosecuted with energy in the mines at Silver Point. There are now thirteen men at work in that district, and ore is being shipped to Jefferson for reduction. Silver Point is situated about fourteen miles west of Belmont.

Sullivan District.

WORK.—*Virginia Enterprise*, June 9: A few mines are at work in Sullivan district. Work was kept going on one or two claims all last winter. One of those days we are likely to hear of a strike in that region.

Taylor District.

ATTRACTING ATTENTION.—*Pioche Record*, June 4: This district is now attracting much attention, and it is on its merit, there being no excitement connected with it. The mines, says the *Pioche Record*, are not mere prospects, but have been worked to some depth, and good quantities of high grade ore are exposed in them. A town has been laid out and many of the vacant buildings in Ward are being taken down and conveyed to the new town in Taylor district.

THE MOUNT CORY BONANZA. *Virginia Enterprise*, June 9: There can be little doubt but a bonanza is about to be hatched at the Mount Cory mine, and Superintendent Patton, of the bonanza mine, has also gone out there. From all accounts the Mount Cory is a wonderful mine. It contains vast quantities of both free-milling and smelting ores. They will have both mills and smelting furnaces at work. All the ores have been so thoroughly tested by actual working that the owners know exactly what they will pay. By means of several tunnels, drifts and crosscuts, they have opened up a vast quantity of ore. All this was done before they made any move toward putting up reduction works, proving everything as they have gone along, and it is impossible for them to have made a mistake in anything. Other important discoveries have been and are still being made in the same region, and the indications are that at no distant day Hawthorne will be a very important mining center. Lumber, a few miles further out on the Carson and Colorado, is already doing quite an active business in the shipment of ores.

ARIZONA.

ROGERS DISTRICT. *Pinal Drill*, June 9: Donahue, Hutchinson & Co., started their new smelting furnace in Rogers district, on Monday last. It works on the World Beater Silver Chief, Manhattan and Johnny Carpenter ores. These mines are the property of F. E. Prosser and Clet, Cedingler. We witnessed the smelting process, which is perfect and the

mixture of ores from those mines forms a combination of all the required fluxes. A specimen of the bullion is to be seen in the store of Caddigan & Co. We judge that the bullion will run \$700 to \$1,000, to silver per ton, and 60 in lead. They can work about 1 tons per day, yielding about \$1,900 in bullion at a cost of \$40 per day.

THE MILL. *Arizona Sentinel*, June 9: The Royal Mining Co.'s mill at Pachuca is proving to be a success. The amalgamator, Mr. Chas. Smith, is entitled to great praise, as he is a test man who has successfully worked the Pachuca ore. The mill gets away with 20 tons in 12 hours, working the rock to above 60. The tailings only assay \$1.50 per ton. A new team has been started hauling ore, and the mill will consequently work day and night to-morrow. Frank Wilson is the able chief engineer of the works.

COLORADO.

BONDERED NEWS AND COURIER. June 9: A gentleman who is thoroughly posted on the mines of Bondered county stated to us on Wednesday that our miners could, between now and the first of June next year, produce two millions of dollars if the owners would let them. To show how they could do it, he gave us the following figures, which we find are verified by those who ought to know: The Yellow Pine mine has in sight \$1,000,000 worth of ore; the Slide has \$300,000; the Prussian \$100,000; the Thorburn, \$200,000 and the Inter Ocean \$50,000, making \$1,650,000 in sight. The smaller mines can bring the amount up to \$2,000,000 easily. He also says that on the completion of the railroad to Caribou, it will be an easy thing for Caribou Hill to produce 50 tons of smelting ore per day. Let us hope some effort will be made to try and get the owners of these mines to work them to their full capacity.

MONARCH. *Cor. Denver Republican*: In about ten days work will be commenced again on the Lexington, owned by Eli Tommala and Geo. L. Smith. This property lies on a direct line between the Madonna and Mount mines. Discovered in 1879, and with such prospecting as was then done on it, showed conclusively that it contained mineral. At different times small shipments have been made amounting to several tons, the returns from which showing from 30 to 80 ounces in silver, and an average of 40 percent in lead.

THE FAIRPLAY LODE was discovered and located in 1878. After passing through a number of ownerships, became, by purchase, the property of its present owner, J. S. Boone, who, in September, 1882, began development. The average returns from shipments have been \$53 per ton, net, clear of every expense. The mine in its present capacity can turn out ten tons of ore per day, and it is expected that when the new tunnel reaches the ore body the output can be doubled. Three shifts are worked in twenty-four hours, eight hours each. The ore, like the other ores of the camp, is free smelting, of the character so much in demand throughout Colorado.

THE MONARCH MINE has resumed shipment the trail being clear of snow. This week three carloads, thirty tons, were shipped to the Grant smelter at Denver. The building of the railroad is progressing steadily, the grading of the highest and most difficult points along the route are being worked upon with vigor, the level and easier portions being left for later on in the work.

IDAHO.

WORK WAS DISCONTINUED. *Wood River Times*, June 9: John V. Purwell and Asa W. Clarke, owners of the Narrow Gauge mines, have had a disagreement, and application has been made for a segregation of interests. This accounts for the recent suspension of work on the Narrow Gauge-Bannack group.

ATLANTA ORE.—Major Pett, Supt. and part owner of the great Atlanta mine, at Atlanta, who is spending a few days in Hailey, received a note from his foreman last night, which read as follows: "Four hundred level all O. K. We cut the ledge last night (on the 28th) and cut six inches of ore." This proves the continuation to this level of the ledge and ore-body formed on the upper levels, and indicates the existence of a bonanza of no mean proportions. Major Pett felt very confident that this would be the case, and he has not been disappointed.

THE ST. PATRICK MINE SOLD.—A letter from the East informs the *Times* that Dr. Hayford, who was a partner of Colonel Adams, who was killed in this city last summer, has just sold the St. Patrick mine, which is situated near Bellevue, to a Baltimore, Md., company, organized for the purpose.

MILBURN FURNACES BURNING. Lee Baker, returned last night from a trip to Milbourn. The Milbourn furnaces are running on Milbourn ore, and turning out bullion steadily; but the town is very quiet, owing to the fact that wages are low and very few men employed.

MORE MINERAL. *Ketchikan Keystone*, June 8: Messrs. J. H. Adams and J. H. Cassidy, two well known and respected miners of Wood River, having leased the Imperial, in Greenhorn Gulch, for a length of time started in on a tunnel above the mouth of the discovery shaft, and followed the vein a distance of 60 ft extracting sufficient ore to pay expenses. About four ft from the breast of the tunnel, which by the way is the very first work of development on the location, a prominent vein of quartz began showing to galena, and it still continues showing in the breast, at time of our visit, fully two ft of solid galena. This extends from top to bottom of the tunnel and an unknown distance beyond. The ore vein is distinctly visible from side to side and top to bottom, sparkling in a luster of brightness. We have seen nothing in any prospect of equal development to surpass this, and are jubilant with the owners in the sense of an extensive addition to the mineral wealth of Wood River.

MONTANA.

SHORT SHIFTS.—*Battle Miner*, June 7: The Poser continues to improve with developments, and is likely to prove one of the biggest properties in the camp. The Montana Copper Co. are producing 20 tons of matte and are shipping a large amount of high grade ore to Europe. Prospectors report the finding of good placer diggings at the head of Pipestone Pass, and that a party who left here 60 days ago are making \$7 per day to the man. Clark's fraction, which lays between the Alice and Magna

Charta properties, is producing some very high grade ore. John Noyes is working his placer, and a lot of this city with a large force of men and with good results. The Silver Bow mill is running on Shoshone ore this week. Rumor of the sale of the Bell Charta, which became current last week, are unconfirmed. It is one of the group of properties which recently passed into the hands of Judge Davis. The Lexington bullion shipment yesterday was one of the most ever made from the camp. Twenty-three bars were shipped valued at \$45,000. A large number of small prospects, lying north and south of Walkerville are being worked this summer. The new three-compartment shaft at the Bell has reached a depth of 40 feet. The Bell smelter continues to produce its 60 tons of matte per day with a single blast running. The winze from the 400-foot south-west drift at the Mountain has penetrated a fine body of ore, which samples, from 30 to 60 ounces. The vein of high grade ore in the east drift, north vein, at the Magna Charta yesterday. The vein is two feet wide and samples \$75. The 250-foot east drift, at the Shoshone has advanced 200 feet from the shaft. The pay streak in the lode is now three and one-half feet wide and pays out a mill average of 60 ounces. The Silver Bow mill commenced running on ore from this mine at noon yesterday.

NEW MEXICO.

BLITZ. *Southwest Sentinel*. The present average daily shipment of high grade ore from the "Old Man" mine at Deming, is about twenty tons, two carloads leaving the Silver City depot each afternoon. Partial returns received from the Hilder-Sueher company upon former shipment of low grade ore have been about \$2,000 each day for the past twenty days. These facts are tangible, and a plain statement of them is worth more than a dozen columns of vague, indeterminate puffing.

BIG STRIKE. A big gold strike was made in the Phoenix mountains a few days ago. Particulars will soon be furnished. They are gold quartz leads, and several have been located to date. Locations are still going on, and the prospects are that it is a very rich find. Look out for another big bonanza in this section.

THE HILDER-SUEHER. At Albuquerque, has about 100 tons of ore in its bins, with ten more carloads on the road.

KINGSTON CONCENTRATING WORKS. *Tribune*: Mr. F. G. Caldwell, representing a company with ample capital, has just completed the main building designed for the reception of concentrating machinery, and proposes to have the works in active operation within the next thirty days. The machinery will be driven by a twenty horse power engine, and for the present will consist of works capable of treating ten tons of ore per day. These works are designed for the treatment of the low grade ores of the camp, and this first plant, if successful, will be added to from time to time as the business demands. Mr. Caldwell informs us that he will either concentrate and return the ore to owners, or ship, at the option of customer. Twenty ounces ore will be available for this process, and can be reduced to the proportion of one ton from six or eight.

KINGSTON. No camp in New Mexico gives brighter promise for the future than Kingston. Not a claim has been developed that has not improved as depth has been gained. Many of the prospects are phenomenal in the yield they have afforded from the surface down. For its age, the Pachuca district has more producing mines than any in the Territory, and some of them are paying handsome dividends beyond their entire cost to the present owners. The North Pachuca and its tributaries, the Middle and South Pachuca and tributaries, the Triple and Terra Blanca and their tributaries, all have along their courses magnificent prospects and paying mines. The whole country appears to be thoroughly mineralized.

OREGON.

MINERAL DISTRICT. *Cor. Redrock Democrat*, June 6: Never has our mining camp seen so healthy an aspect as at present. At first regarded with suspicion and distrust it has now, owing to the energy and industry of its few pioneers, gained the confidence and favor of capitalists to a large degree and can enlist their aid to a greater extent than any mining field of the same age on the coast. Though prospecting is being vigorously pushed and rich discoveries are of frequent occurrence, we have none of that wild unwholesome excitement, which has proved the curse of so many promising fields, and brought ruin to so many sanguine persons. The steady determined industry exhibited by our mining population reflects credit on them, and augurs well for our future, and if our camp ever attains the position, present prospects predict, it will be gratifying to know their energy and perseverance has not the reward it so justly merits. It is useless to attempt enumerating our many valuable mineral deposits, but I consider myself perfectly justified in advising any person looking for a safe and profitable investment to visit us; what we now require is men of money and energy; to such our camp offers splendid inducements.

UTAH.

DANA GROUP. *Salt Lake Tribune*, June 6: The Dana group of mines at Park City, lying west of the Ontonagon, comprises 25 patented claims covering about 150 acres of surface. On these claims, to this date about \$78,000 have been expended, and now the property is in a fair way to soon make itself known by the ore output which must follow the development to be made from this onward. Mr. Daly resigned his position as superintendent of the Crescent mines that he might look after his interests in the Daly group. He will sink a two-compartment shaft to a depth of several hundred feet for the purpose of developing a vein which he has been prospecting by tunnels for several years, and which has been proved a distance of 5,000 ft, showing ore running from \$200 up to \$1,800. He has between 10 and 15 tons of ore on the dump. The vein is a strong and good one, and there is little doubt but the property will prove a most excellent one when properly opened. Mr. Daly has been in Park City the past three years, and has had extensive experience in mining, having come to Utah in 1870. He afterwards went to Nevada and California

The Sawtooth Country.

A correspondent of the Salt Lake *Tribune* says: I got into this part of the country a week ago to-day, and to say that I was surprised at the prosperous outlook of this district, would be drawing it quite mildly, considering that I had been led to expect, from reports by those "know-it-alls," that a traveler will often run across on Wood River, I had been told that the "upper country," as Vienna and Sawtooth are called, was a district where no paying mines existed, where ores were terribly low grade, and base at that; where "copper mills" were being remodeled to crush the product of the country; where snow was twenty feet in depth, and salt bacon one dollar per pound, and other eatables in proportion. Such reports must originate from old-time members of a lying club. Notwithstanding the drawbacks mentioned, I came right along through Wood river and reached the summit of the Wood River and Salmon river divide, and from that elevated position I saw bare ground in all directions, excepting upon the high peaks and upper part of the gulches surrounding the valley of the Upper Salmon. Descending the mountain, I made my way toward Smiley canyon, and until I reached a point within four miles of the town of Vienna, I encountered but very little snow. As it was early in the morning the crust was sufficiently hard to bear one's weight, and no difficulty was experienced in reaching Vienna. I found the town just starting in for a summer's campaign. Everybody seemed to have some building to fix up, and the inhabitants, generally, had the appearance of a go-ahead class, which is characteristic of towns that have something like a solid

competent to judge estimate at least \$150,000 blocked out ready for shipping.

Yet, in the face of these facts, there are parties who will say there is no backbone to the Sawtooth country. But never mind, "Truth crushed to earth will rise again," for the districts of Vienna and Sawtooth never had a brighter future ahead than they have to day.

About fifteen inches of snow yet remain on the ground around Vienna city. The streets are bare and the snow is disappearing very rapidly. Our mail arrives and departs via Cayuse. Pack trains are coming into town and wagons will very soon follow. The roads will be in good condition in ten days or two weeks, to this place.

Prospectors coming to Sawtooth and Vienna can come right along now, and by the time they get here and get outfitted the snow will be sufficiently gone to allow of prospecting the surrounding country.

Paradise District, Nevada.

For some time past J. V. McCurdy, an experienced and practical mining and mill man, has been at work with a view of starting up the Paradise valley mine and mill, which have been shut down for over two years past. After considerable trouble and expense, and several trips to San Francisco and the Paradise mines, he succeeded in purchasing the Wild Goose mine for the Paradise Valley company, and he is now making arrangements to commence work on both mines and get the Paradise Valley company's mill in running order. It is estimated by experts, who have examined the Paradise

Minnesota District, Arizona.

From the *Mohave Miner* we take the following: The Minnesota district was formed December 27th, 1880, and probably less is known of it than any other district in the county. This is probably due to its isolated position, lying as it does out of the usual run of travel. The nearest settlement or mining camp to the district is El Dorado canyon, which lies on the opposite bank of the river from the district and about eight to twelve miles from the nearest mines. Mineral Park is some forty miles from the district in a southerly direction. The district is some twenty miles square and is bounded as follows:

Commencing at Johnson's rock on the Colorado river and thence running east twenty miles; thence north twenty miles; thence west to Roaring rapids on the Colorado; thence down the river to the place of beginning.

The general character of the country may be termed desert in the truest sense of the word, the entire area included in the boundaries of the district being totally devoid of wood and water and containing nothing in the shape of vegetation but cactus and a little brush, except on the bank of the Colorado where plenty of cottonwood and mesquit is found. As to the mineral wealth of the district very little is really known so far, as very little prospecting has been done. It is well known, however, that a great many well defined ledges varying in width from two to 20 feet and more do exist, and that they are mostly of low grade, some of them containing, however, bunches of very rich ore. What little work has been done in the district has con-

tons of ore was taken and hauled to the Lincoln mill, a distance of twelve miles, for reduction. This ore worked \$120 per ton. The vein from which it was taken averaged about eighteen inches in width, the ledge being very spotted.

Etiwanda Canyon.

We present on this page a very fine view of the Cascades in Etiwanda canyon. It represents a portion of the scenery on the headwaters of one of the streams in the Cucamonga mountains, that furnish water for the Etiwanda settlement. This canyon was formerly known as Day canyon, but more recently it is called Etiwanda canyon, after the settlement planted by the Chaffee brothers and which has become of prominence in southern California during the past year.

BEER AND BUNNING IN MINING CAMPS.—"A year ago in the University of Berlin, now in a mining camp of the Wasatch Rocky mountains selling cigars for a short bit." That is how a young man put it to us in Park City the other day. We couldn't help asking (to ourselves) why sell cigars at all? And the same query touching cigars and beer and spirits occurred to us as we passed in and out (on business) of the score of saloons along the main street of that town, making a miserably poor living, while the hills are full of fortunes for the energetic worker. Living a camper's life, cooking and washing for one's self, without any of the comforts or requirements, on the slim profits of selling beer. It would make a new town of it, if nine out of ten of the saloon keepers would close out to the

CASCADES IN ETIWANDA CANYON, SAN BERNARDINO COUNTY, CAL.

foundation to build upon. Quartz camps, as a general thing, take a longer time to come into prominence than a galena district, but when they do reach a paying position, they remain there a greater length of time than those districts, where a ten ton freight car will carry all the ore extracted in three years' development work. These quartz mines go down to the deep, and thus far have proved themselves to be much richer and the ore more abundant as depth is attained.

A fine twenty-stamp Frasier & Chalmers' dry crushing mill is fast nearing completion at the outskirts of the town. There is plenty of life around the Vienna company's mill, which, under the able superintendency of Captain Henry Guyer, who informed me that the mill would commence dropping stamps within the next three weeks, or probably earlier, all owing to how soon the roads would become passable for heavy freight wagons. The road winds its way up past the basin and is intended for hauling the ores of the Mountain King, Solace, and Vienna mines. These three mines were the only properties of any great importance developed during the past winter, with the exception of the Nellie group, which closed down along the middle of the winter, owing to an avalanche that swept over the cabin, killing two of the men. Several hundred tons of ore are on the dumps, and in the ore house of the Mountain King mine, awaiting the arrival of teams. Many thousand tons more are blocked out in the mine, ready for shipping, but until the ore can be hauled away to the mill, it will not be extracted. The Vienna property has also many hundred tons awaiting the arrival of the ore haulers. The Solace mine has developed wonderfully well this winter. Men

and Wild Goose mines, that there is at least 10,000 tons of good milling ore in sight in both mines, with a fair prospect of an unlimited supply of similar ore. This ore will be taken to the Paradise mill, on Martin creek, for reduction. The mill was built for dry crushing and there are roasters attached to it, but it will be changed to a wet crusher, as the greater part of the ore does not have to be roasted.

The resumption of operations on these mines is of great importance to Paradise merchants and farmers, as it will give employment to a number of men and put several thousand dollars a week in circulation. The Paradise Valley, during the short time it was worked, produced about \$500,000 in bullion, and unless the mining men, who closely examined and sampled it, are greatly mistaken, there is ore enough in sight to produce as much more. The Wild Goose mine is on the same lead as the Bullion of Paradise.—*Silver State*.

TUSCARORA NOTES.—The Basin Company's mill is nearly completed and ready for operation. It will start up sometime about the middle of the month. There is a considerable amount of ore already on the dump, and enough more in sight in the mine ready for stoping to keep the stamps running during the season. Present prospects indicate that the mill will render a good account of itself before the snow flies again. If the Basin Company makes the success which the present prospects justify the anticipations of, it will give an impetus to mining in a section of our district which has heretofore been sadly neglected, but which many experienced miners believe to contain the largest and most valuable mineral-bearing ledges in the vicinity of Tuscarora.

sisted in taking out a few of these rich bunches and taking the ore across the river to the Lincoln mill, at El Dorado canon, for reduction. About the first location made in the district was the old Jennie mine, which was located in December, 1880, by John Hewes, J. Baer, and others. These parties took out some rich rock and had it worked at the Lincoln mill. The ore worked so well, that the Lincoln Company immediately bought the claim, paying the owners \$1,000 each for their interest. The company at once put some men on the mine, who sunk a shaft some thirty feet deep besides doing considerable surface work, and at the end of about two months had cleared between six and seven thousand dollars. About this time the company became involved in litigation, which resulted in the closing down of the mill and everything connected therewith. Most of the ore taken from this claim during the short period it was worked by the Lincoln Company milled about \$425 per ton, the ore being rich in horn silver. There is two feet of ore at the bottom of the shaft, but it is of a low grade, the rich pocket evidently not going down to that depth. The company having become completely "busted," to use a homely but expressive phrase, this claim was neglected until on January 1, 1883, it was re-located under the name of the Ontario by J. Baer and J. H. Barker, Baer being one of the original locators of the mine, who proposed to do some work on it this year. This mine is eight miles from El Dorado canyon, over a fair road.

Another mine which has produced considerable ore is the Weaver, which was located a few days after the Jennie mine by John Weaver and others. The work done on this claim consists of a shaft and tunnel, from which some forty

tenth, shut up their shanties, and go to work, even for wages, if they couldn't strike out for themselves. The same is true of all other flourishing mining camps. You can always tell where the "boom" is, for every second door is a saloon, and not one man in a hundred of those who thus follow and prey upon the mining industry make a half decent living out of it, while there are very few of them who are not ashamed of it. There is not even money to be made out of it; and if not that, or some sort of a comfortable living, what is there?—*Salt Lake Tribune*.

THE TIFFIN GROUP SOLD.—The Tiffin group of claims, in Narrow Gauge gulch, Deer Creek, which comprises claims known respectively as the Tiffin, Tiffin No. 2, and Seneca, and which adjoin the Forest Creek group on the west, were sold yesterday to the representative of some Tiffin, Ohio, capitalists, for the ridiculously small sum of \$3,000 - \$1,000 for each claim. This figure is much below the actual value of the property, but the Knukel Brothers, who owned it, also own a number of adjoining locations, and they sold the Tiffin group in order to get moneyed men interested in the District.—*Wood River Times*.

SCIENTIFIC MOVEMENTS IN CINCINNATI.—There has been unusual awakening in scientific circles in Cincinnati during the past few months; a polytechnic school has been organized; a State forest association formed, with its headquarters in Cincinnati; and courses of popular lectures on chemistry, zoology, botany and history, have been given at the afternoon school in popular science and history.

THE ENGINEER.

The New Egyptian Canal.

The New Egyptian canal seems to be a foregone conclusion, not so much on account of the international complications attending the present Suez canal, but because of the press of business seeking that way of transit to and from the Atlantic and Indian oceans. A special meeting of all parties interested will be held in London some time during this present June for the purpose of considering the three schemes for the canal, which are as follows: First, a new canal parallel with the one now in existence, to cost £6,000,000. The second for a canal from Alexandria up the Nile, passing north of Cairo to the Red Sea, and the third south of Cairo to the sea. Each of the latter, it is estimated, will cost £12,000,000. A majority of the committee favor the Alexandria route. French opposition to these schemes is ridiculed, and the monopoly claimed by M. de Lesseps for the Suez company is considered untenable. An English syndicate has already received offers for the whole capital required. The present canal is bringing in about \$50,000 per day, hence there can be no doubt but that with the constantly increasing rate of business, a second canal will pay from the start. No nation has the title of interest which England possesses in the undertaking, and there is no doubt but that English capital will put it through at the earliest day practical.

A NEW KIND OF MOUNTAIN ROAD.—An exchange says that a tramway is to be built up Pike's Peak, which will overshadow the Mount Washington railway. The plan is to construct three of these tramways, each nearly three miles long, one beginning at the end of the other. The first will start at the rear of the iron springs, at Maniton, Col., and the last will be terminable in front of the signal station on Pike's Peak, an elevation of 14,200 feet. The supports will be made of trees not less than eight inches in diameter, and about twenty-four feet high, braced above and below. On these an endless wire cable, of one inch bore, will revolve, and upon which will be fastened, at intervals of about 100 feet each, a large covered armchair, in which two persons can comfortably sit. This will be suspended about eight feet from the ground, and pass at entering and discharging points along a movable platform to load and unload, without stopping. The lower section will be propelled by an engine at the lower end. The center one will be driven by water power, utilized on the mountain side through a turbine wheel, and the third by an engine erected on the summit of the peak.

STRENGTHENING A FOUNDATION.—An interesting way of strengthening a weak foundation was recently tried on a new building that suddenly commenced to settle. The excavation for the walls had been carried down until a mixture of coarse sand and gravel was found, which was deemed suitable. During a heavy rain water found entrance to the cellar, when the sinking resulted. The building was braced, the cellar drained, and then the inside wall of the foundation was uncovered down to a little below the bottom. A λ -shaped piece of masonry having a height of about twice the width of the base was then built, the bond between it and the wall being carefully looked to. After this had been finished upon the inside, it was repeated upon the outside. The base of each of these pieces was equal in width to that of the wall, so that the operation practically trebled the bearing surface of the foundation. It may be well to add that the water will not again be permitted to enter that cellar, as every passage way has been securely closed.

THE ST. GOTHARD TUNNEL.—Investigations have been made of the cause of weakness in the parts of the St. Gothard tunnel where the vaults were crushed, and it is thought that the accident must be attributed to the action of damp air upon the shists and gneiss, and to the decomposition which resulted therefrom. The presence of anhydrous sulphate of lime, or karsenite, was also an important agency, its transformation into gypsum being followed by a dis-aggregation which renders the rock incapable of sustaining its pressure. Other hypotheses have naturally been framed, but this is considered as the most plausible.

THE MERSEY TUNNEL.—Rapid progress is now being reported in connection with the tunnel of the Mersey railway, England, and nearly 700 men are said to be employed, both night and day, working in eight-hour shifts. The tunnel will be three and one eighth miles in length. The drainage headings are about 100 yards in advance of the main headings, and will act as reservoirs, into which the water from the main tunnel will be drained and run off to both sides of the Mersey, where pumps of great power will raise the water to the surface.

THE NEW BRIDGE across the Firth of Forth, now building, will, when completed, be among the most remarkable bridges in the world. The main girder will be within a few feet of a mile in length, and will rest upon round cylindrical piers, each of which will weigh 16,000 tons. It will, of course, be high enough for all vessels to pass underneath, and about 42,000 tons of steel will be required in its construction. The estimated cost will be \$7,500,000.

USEFUL INFORMATION.

Rendering Cement Airproof.

A method of rendering cement impervious to air has been successfully practiced by Herr C. Pascher. This experimentalist claims to have found that the only way to render cement unalterable by atmospheric influences is by the application of a cold solution of one part of sulphate of iron in three parts of water. The articles to be protected should be left to soak in the solution for twenty-four hours, when they take a greenish-black tint from the hydrated protoxide of iron. The absorbed solution is decomposed in the interior of the cement, which is increased in weight ten per cent. All the pores of the mass are thus stopped by the hydrate, and as this compound is not attacked by air, the cement itself becomes impervious. Cement facing may be washed down with several coats of the solution. When dry, the cement may be covered with a wash of ochre, or by a solution of sulphate of alumina. If a greenish-white face is desired, the surface may be first washed with a solution of chrome alum, and then with soapuds. Either of these coats may be painted or colored in distemper. It has been observed that when oil colors are laid upon bare cement they easily peel or scale off; but this inconvenience may be avoided by washing the cement thoroughly with soapuds, and when perfectly dry rubbing with a brush or linen cloth until the surface shines. Afterward the oil colors may be applied in the usual way.

ORIGIN OF THE NEW YORK AND BROOKLYN BRIDGE IDEA.—The question by whom the idea of erecting a bridge between New York and Brooklyn was originally conceived, is apparently settled by a communication to the *Journal of Commerce*, in which journal, moreover, the first public mention of the scheme was made. A correspondent of that paper writes: "In the month of February, 1853, my uncle, the late John A. Roebling, accompanied by his wife and son Washington, then a lad of fifteen years, came from Trenton to my house in Hicks street, South Brooklyn, to attend the christening of my infant daughter Amelia. Returning in the afternoon by the Hamilton ferry, the boat was caught in the ice, and drifted round in a helpless condition for three or four hours. A boat load of soldiers who were east away from Governor's Island were rescued on the trip. Mrs. Roebling was in great anxiety of mind, having left an infant child at home. Mr. Roebling then took a solemn vow, in the presence of the hungry, half-frozen passengers, that if his life was spared he would yet build a bridge across the East river. * * * His vow and the crowning idea of his life have been carried out, not by the father, but by the son who stood so nobly by his side."

POSSIBLE CAUSE OF FIRES.—Are not some fires of apparently inexplicable origin to be explained upon the theory of Prof. Magnus, that iron is combustible just as grain dust is explosive, when mixed with air in certain proportions? The simple experiment of Magnus is thus described: "The pole of a good sized magnet is approached to a mass of iron filings, a bunch of which readily attaches itself thereto. In this condition, being not only in a highly comminuted state, but carrying a large quantity of air mechanically entangled in the loosely aggregated mass, the iron is in so favorable condition for combustion that the approach of an ordinary spirit lamp is sufficient to inflame it—in fact, it burns readily and continuously like any ordinary combustible." We can see no reason why these necessary conditions should not occasionally occur in shops where mixed work is done, and the absence of wooden shavings or the like from the neighborhood of a light would be taken as evidence that the cause of disaster did not proceed, even remotely, from the presence of the light.

NEATSFOOT OIL.—This oil varies in quality as regards what part of the feet it is taken from. The mode of obtaining it is as follows: The feet and hoofs of neat cattle are cut off about eighteen inches above the hoof, denuded of skin and slit up longitudinally. Near the hoof is a small mass of soft fat, which is scooped out with the knife, and set aside for the preparation of the best quality of oil. The hoofs are washed in cold water, and then boiled in open pans set in brickwork, and heated by a fire beneath. A certain quantity of oil is thus boiled out of them, and when skimmed off, forms an inferior grade of neatsfoot oil. After about three hours' boiling, the tissues between the horny hoof and the last digit bone are sufficiently softened to allow of the latter being easily scooped out of the hoof with a knife. These "cores" consist of bone, gelatinous matter, and fat, and together with small pieces of fat, previously alluded to as being removed by the knife before boiling, are put into a separate pan of fresh water, and all boiled together for the extraction of the oil. This forms the best kind of neatsfoot oil.

AN ANCIENT GREEK BRONZE HORSE.—Grecian reports state that recently, as some Ægean fishermen were fishing for sponges, near Delos, they came upon an ancient bronze horse at the bottom of the sea, about two fathoms and a half deep. It is described as being of colossal size and almost covered with shell fish. After much effort the fishermen succeeded in break-

ing off one of the feet of the horse, and took it home to Egina, where they offered it for sale. The matter came to the knowledge of one or two archeologists, who purchased the equine bronze foot. This they found to be of excellent workmanship, and it appears clearly to indicate that the equestrian statue is a valuable relic of antiquity. It has accordingly been determined to endeavor to discover the whereabouts of the horse, and to fish it up, if possible, entire. It is suspected that the statue is probably an ancient votive offering, which was once set up in the island of Delos. The interest felt in the matter is all the greater as, if the work is recovered, it will be the first bronze horse of a large size which has been preserved since the classical age of ancient Greek art. There are very few equestrian statues preserved from ancient times, and hardly one which can be demonstrated to be of Greek origin.

WATER POWER OF THE ALPS.—It is now proposed to use the enormous water power of the Alps for working electric railways in Switzerland. Operations are understood to be in progress now to connect the towns of St. Moritz and Pontresina by an electric railway four and three-fourth miles long, the motive power to be supplied by the mountain streams. Should the experiment succeed, the undertakers of the railway will extend it to the north for a distance of some forty-seven miles, and in a southerly direction for about thirty miles, and thus effect a second junction between the Swiss and Italian railways.

MUCILAGE FOR ENVELOPES.—Take a quarter of a pound of gum Arabic, dissolve it in one pint of boiling water; add a piece of borax as large as a walnut; when thoroughly mingled with the water—which can be done by frequent stirrings—bottle in a large-mouthed bottle; through the cork pass a hen's feather, and you will have a pint of mucilage as good as the best; shake the bottle occasionally for three or four days after it is corked. If the weather is hot, a tablespoonful of alcohol will prevent all mold.

IMITATION CAOUTCHOUC.—Dankworth and Landers, of St. Petersburg, have invented a composition which is elastic, tough, waterproof and insulating, and which is applicable to nearly all the purposes for which India rubber is used. It is composed of a mixture of wood and coal tar, linseed oil, ozokerite, spermaceti and sulphur, which are thoroughly mixed and heated for a long time in large vessels, by means of superheated steam.

GOOD HEALTH.

Is a Cold a Fever?—A New Theory.

The theory that colds are the result of exposure to cold or damp air is generally accepted. Indeed, most persons afflicted with this disorder are able to trace its origin satisfactorily to themselves at least, to some undue or unusual contact with outside air. They seek no other explanation. In the columns of the *Popular Science News* Dr. Page, of Biddeford, Me., undertakes to show the fallacy of such a course of reasoning. That his theory is new to most people is no proof that it will not hold good. Having made the subject of colds a special study for ten years, he concludes that the ailment which is universally called a cold is in reality a fever, and is directly caused by indigestion or impure air. He says: "Foul air prevents the purification of the blood; hence the accumulation of impurities which in their exit give rise to the symptoms popularly supposed to indicate cold. Hot living-rooms render impossible the digestion of more than a little food, and that of the plainest sort, by making only a little necessary."

Indigestion results from eating improper food, or some degree of excess, the excess being either positive or relative, according (1) as the skin is more or less sweltered with clothing, (2) the lungs more or less outraged by bad air, and (3) the entire organism more or less invigorated by fresh cold air. It is unquestionably true that when, by reason of wrong conditions, the system has become ill-conditioned—that is when there are impure matters to eliminate—some chance exposure to a bracing atmosphere may so invigorate the organism by the presence of fresh air in the lungs and its touch upon the skin that the process of elimination begins, and but for the return to the close overheated atmosphere of the home, this process would often be completed all unconsciously to the individual, who now makes the great mistake of 'confounding the cause of his recovery with the cause of his disease.'"

Dr. Page disapproves of covering the body with a superabundance of clothing. People sometimes take cold by putting on flannels. Care should be taken to regulate clothing by the weather. In conclusion the doctor says that if it could become popularly known that the symptoms observed in cases of "cold" were evidences of an effort on the part of the organism to eliminate impurities which have been collecting perhaps for months, and that "fasting, fresh air and exercise are nature's triple panacea" for the disorders, a very great proportion of all severe sicknesses would be prevented. *Popular Science* remarks that without presuming to question the efficacy of the doctor's remedies for colds, we think there are compara-

tively few people possessed of sufficient temerity to discard the winter flannels with pneumonia or a kindred disease staring them in the face.

THE DELUSION OF ARSENICAL BEAUTY. says the *London Lancet*, has broken out afresh. That paper utters a warning cry against the mischievous error that "arsenic in small doses is good for the complexion." It is not difficult to imagine the risks women will incur to preserve or improve their "good looks." No more ingenious device for recommending a drug can be hit upon than that which the authors of this baneful prescription of "arsenic for the complexion" have adopted. Suffice it to recall the fact that for many years past chemists and sanitarians have been laboring to discover means of eliminating the arsenical from the salts coloring matter of wall papers, and certain dyes once largely used for certain articles of clothing. It is most unfortunate that this hopelessly antagonistic recommendation of arsenic to improve the complexion should have found its way into print. Those who employ the drug as advised—and there are many either already using it or contemplating the rash act—will do so at their peril. So far as they are able, however, it will be the duty of medical men to warn the public against this pernicious practice, which is only too likely to be carried on secretly. It is not without reason that we speak thus pointedly, and urge practitioners to be on the *qui vive* in anomalous or obscure cases.

SPECTACLES.—There is no particular age at which spectacles are required. As a rule, men need them between forty five and fifty, and women after forty. Many persons object to using spectacles because they think it makes them look older, and so injure their eyes by straining them, when if they had used spectacles it would not have happened. When one cannot see clearly by gas light or lamp light without holding the object further from the eyes than is agreeable or natural, then they require spectacles and are injured by not using them. Often the injury is such that no optician can remedy it. Another very good test of the eye to see if there is any difficulty at first sight in distinguishing the figure 3 from 5 in ordinary reading by ordinary light. If there is, spectacles are needed.—*Herald of Health*.

THE RAPID INCREASE OF INSANITY in this country is fearful to contemplate. Insanity costs the state of Massachusetts \$800,000 a year. Every insane person represents a dead loss of at least \$5,000 and an indirect loss of much greater. This represents an outlay of \$200 a year for as many years as the patient lives. Insanity is increasing in this State rapidly, and fresh inquiries are made as to the best way of treating the insane. The congregated system is denounced and the cottage system advocated. A new plan for the treatment of the insane is demanded here. Probably no State in the Union is so generally affected in this direction, as California.

PETROLEUM—ITS MEDICAL PROPERTIES AND USES.—The United States Dispensary, a standard work with druggists, says (page 1,582) that "In Germany petroleum is highly extolled as a remedy for tapeworm, and that it was often used with advantage in epidemic cholera by Dr. Androsky, of the Russian army." In fact, from the earliest discovery of petroleum to the present day, there has been a strong conviction that the good qualities of crude oil have not been appreciated, and that it undoubtedly possesses great medical properties. As a liniment it is certainly preferable to any of the oils. Its great penetrating powers and its freedom from rancidity, are advantages which no other oil possesses in so high a degree.

A CURE FOR BRIGHT'S DISEASE.—General Robert C. Schenck, formerly Minister to England, is now enjoying excellent health. A year ago, it is said, the doctor declared him to be dying from Bright's disease. "You have been too high a liver," they said; "but if you will come down to a prescribed diet, we may possibly save you." "What is the diet?" he asked. "Milk and tomatoes; and you mustn't touch anything else for a year." He agreed to it, so the story goes, and is now perfectly well and able to eat and drink whatever his appetite craves.

SMELL OF PAINT.—The *Herald of Health* says this disagreeable and unhealthy smell may be got rid of or greatly modified as follows: Slice very finely several onions, place them in water in the center of the room; close the doors and leave one window up a little for a slight change of air, and let them stand for a few hours, when the smell will have nearly all gone. If you have no onions use a handful of hay in the water, in the same way. These remedies are simple and always obtainable. If the room is very large, use two pails and double the quantity of onions may be used.

POISONOUS COLORS IN FOOD.—A new law has come into force in Germany, prohibiting the use of poisonous substances to color any food designed for consumption, or for the wrappers enclosing any article of food. The law extends, also, to the employment of any poisonous material in toys used for playthings for children, and in paper used for wall decoration, or dress material. Such a law is needed in some other countries besides Germany.

Dividend Notice—Silver King Mining Co., S. F.
Mining Partner Wanted—"B. S.", San Francisco.
The Harmon Seminary—S. S. Harmon, Berkeley, Cal.

Passing Events.

The virtual bursting of the Lower California placer mining bubble is chronicled this week. The excitement was quieted much more quickly than such things usually are, not more than a month having elapsed since the announcement of the discovery of the mines. Now we hear there is no water to work the mines, and that they are worked out any how.

The conquering of the Arizona Indians by General Crook, who followed the murderous bands into Mexican territory, surrounded and captured them, with the chiefs, women and children, is a cause of great congratulation to all who desire to see the development of the Southwest go on as it should. For Arizona, particularly, the news is good, but New Mexico and the northern states of Mexico are fields for the adventurous prospector as well, which, however, were more or less dangerous while these hostiles roamed the land.

There is not much to record aside from this except what we elsewhere refer to. The mining business of the country is rapidly advancing in material prosperity, and, what is more, is daily becoming more generally recognized as a legitimate field for the investment of capital, the element of gambling formerly connected with it being generally eliminated.

An Arrastra Mill.

It is pretty well understood among those who work gold ores that there is nothing which can beat the common arrastra as an amalgamator. The only objection to it is its lack of speed, but perhaps that is really one of its elements of excellence after all. It may be that time is really a more important factor in amalgamation than it is usually credited with; and that one of the reasons of lack of thoroughness of more modern appliances is that they are constructed to hasten matters somewhat too rapidly. Whatever the reason, the old arrastra holds its own as an amalgamator, and many hundreds of them are doing service all over this coast, mainly for miners with small claims of their own.

There is a regular arrastra mill business at Dos Cabezas, Arizona, owned by "Arrastra" Johnson and E. F. Foster, a description of which will interest many readers. The mill consists of 16 horse power engine and 8x8 Dodge rock breaker and four arrastras. The arrastras are each 9 feet 6 inches in diameter, and when the bottoms are new are 8 inches deep, and on each arrastra is a pulley 8 feet in diameter and run by a 6 inch belt. All four arrastra belts run on one upright pulley that makes 3 revolutions to 1 revolution of the arrastras; and the upright pulley is driven by spur and bevel gear.

The engine makes 160 revolutions, the pulley that drives the spur wheel 135 revolutions, the upright pulley 27 revolutions and each arrastra 9 revolutions per minute. The mill runs so smoothly that one outside of the mill can hardly hear the mill run, and with 15 pounds of steam the engine can run the four arrastras, and grind 5 tons of hard gold quartz in 24 hours. When the rock breaker is working about 30 pounds of steam are used; only one cord of wood is used in 24 hours.

Each arrastra runs 1,250 pounds of ore per batch, and two batches in twenty-four hours. After the ore has been ground four hours the quicksilver is put in. More quicksilver is needed at the beginning of a run than afterwards, and too much quicksilver is almost as bad as too little. Every batch must be prospected to see how much is needed, for some kinds of ore will, where the batch is thick, raise all the loose quicksilver and the amalgam will remain in the crevices, so that when too much quicksilver has been put in once the next batch will not need so much, or probably none at all. Other kinds of ore will not raise the quicksilver at all, so that every batch must receive just enough to amalgamate the gold the ore contains, usually about four ounces of quicksilver are used to one ounce of gold.

After the ore has been ground nine hours it is ready to thin up, and just enough water is added to the batch to settle the sand a little and then run till the sand is ground, when the batch is ready to run off. By this plan all the gold is amalgamated and settled and caught in the crevices. One of the arrastras is arranged so that silver rock can be run; it is connected to the boiler by one-half inch steam pipe and silver ore can be worked to as high a percentage in this arrastra as in any other pan. The steam pipe and cover for the arrastra cost but a trifle. A drag of iron of about 200 weight helps to grind and also helps the amalgamation.

Electric Light in Arizona.

EDITORS PRESS:—The business of electric lighting seems to be making progress in this Territory, both for public and private use. Organizations having recently been perfected in Tucson, Phoenix and Prescott, under franchises granted by the Brush Electric Light Company of Cleveland, Ohio, and the Swan Incandescent Electric Light Company of New York.

A Brush-Swan Electric Light Company was incorporated here a few days since, with a capital of \$50,000, comprising some of the leading citizens of Prescott. The Howard Smelter and Mining Co., the United Verde Mining Co. and the Conger Mill and Mining Co. are about to adopt the Brush Light for the illumination of their works. It is said that other places are considering favorably these combined Brush and Swan lights.

B. W. CROWELL.
Prescott, June 7th, 1883.

THE surveyors on the Oregon and California extension, from Corvallis to the junction, are still engaged in running preliminary lines. They are now between Monroe, Oregon, and the junction. In another week they will be ready for locating, when grading can be commenced.

Reduction Works.

The establishment of smelting works, ore samplers and mills at various points along railroad routes is one of the industries now being inaugurated which is destined to work great good to the mining interests. There are many localities where men have been long at work where their efforts have been greatly retarded by lack of means of reduction for their ores. Miners in small camps have been unable to work their ores to advantage, and have left mines idle which would pay good profits. Custom mills with no competition and no camps, when men could go nowhere else, have been apt to get most of the yield of the work, leaving the miners out in the cold.

The fact of there being a market for ores in any region is greatly to its advantage. Men of limited means, with an opportunity of disposing of their ores, can do profitable work where heretofore they have struggled along for years. Capitalists are seeing that there is a chance for investment in these works and a chance also of getting hold of good claims at reasonable prices. We hear of sampling works being contemplated at several points where ore purchasers and miners will be accommodated. The mining community will be greatly benefitted when such establishments become still more numerous. An opportunity to come into the market with ores is all many of the miners want, and thousands of new mines will be opened and old ones more thoroughly developed.

Mining Surveys.

It has been officially decided that applicants for mining patents are not bound to note on the plat, and in field-note conflicts with unofficial surveys. And, moreover, failure to comply with the regulations of the Surveyor-General does not necessarily annul a survey unless the same fails to comply with the law. In a recent case the plat and field notes of a survey failed to show a conflict with another mine, although the latter had been previously surveyed, and they neglected even to indicate a thirty feet tunnel lying within the limits of the claim. By reasons of the omissions the man who patented was unable to tell by the plat and field notes that the claim in any manner conflicted.

The Commissioner of the General Land Office rules that there is nothing in the regulations that would require a deputy to note conflicting surveys other than those made under direction of the Surveyor-General, and this prior survey was a private one. The existence of such a survey in the present instance may have been well known, and it could therefore have been readily noted, but such is not always the case, and to require that every survey, whether of record or not, shall be noted would in many cases work unnecessary hardship, particularly if a failure to recognize such survey was held to invalidate the notice given to adverse claimants.

The Surveyor-General may make regulations for the guidance of his deputies in the performance of their work, but a failure to comply therewith does not necessarily annul a survey unless the same fails to conform to the law.

The Commissioner thinks the published notices in this case were sufficient to provoke inquiry, and have owners hunt the matter of conflict up. That is what publication is for. It was admitted the published and posted notices were read, but for some reason no protest was made at the proper time.

The Secretary of the Interior has directed a recognition of mining claims of settlers upon the public lands in Montana ceded by the Crow Indians under agreement made June 12, 1880, and ratified by Congress April 12, 1882. The Secretary holds that these lands, being ceded by definite boundaries, become public lands upon the date of the approval of that act of ratification, and from that date the legal rights of settlers and claimants took effect.

A NOVEL BANTER.—A Truckee wood-chopper throws his gauntlet in the face of all who can swing an ax scientifically, as follows: "I hereby challenge any man on the Pacific Coast to cut logs for ten hours, for from \$100 to \$200 a side, the match to take place in three weeks from the signing of articles, and to be within ten miles of Truckee."

A 10-stamp custom mill is soon to be erected at Clinton by some Bodie gentlemen, to work the ores from the Silverado and other mines that have ore in their dumps. The mill will be hauled from Bodie.

The Campbell Process.

A New Method for Treating Refractory Ores.

Of metallurgical processes on this coast we have had a good many; and as these processes have been numerous, so also have they been varied in kind, having been made up of the good, bad and the indifferent. We have had the well meaning but ignorant empiric, essaying a business for which he was but little fitted, either by education or experience; the Fryer fiasco furnishing a notable example of this kind. Then we have had the scientific fraud, the man Tichnor standing pre-eminent as the representative of the purely bogus. But while some few adventurers have so sought to impose their worthless or fraudulent devices on the mining public a much larger number of honest and capable experimenters have entered the field, and by their well directed and persevering efforts greatly advanced the business of practical metallurgy. We have only to recur to the early history of ore crushing on this coast to appreciate the gains that have been made in this department of mining. What would be thought of the man now who should undertake to pulverize gold-bearing quartz with an old fashioned bark mill? And yet the writer was witness to just such an attempt made in this city years ago, and that by a man who was then considered *au fait* at the business. The mill did not grind up much quartz, but we have a distinct recollection that the quartz ground up the mill in a very short time. While this incident illustrates how we have progressed from barbarism to enlightenment in this arm of the service, it may safely be said that the chemistry and metallurgy of the business have more than kept pace with its mechanical advancement. But, while we have accomplished so much, and this Campbell process promises a great deal, persistent and intelligent experiment of this kind lies in the direction of one of our sorest needs.

It is every year becoming more and more apparent that our most productive, permanent and profitable mines are to consist of those yielding large quantities of rebellious ores. Incalculable and to the unmined incredible are our resources in this respect. They abound in nearly every district throughout the vast expanse of our mineral domain. They stretch almost continuously along both slopes of the Sierra Nevada for a distance of nearly 400 miles. Even in the Coast Range we have immense and valuable deposits of this kind; and what we have in California and Nevada is duplicated in Colorado, Montana and New Mexico and largely obtains in all the other States and Territories of the Far West. Rich lodes without number remain everywhere untouched, because of our inability to successfully handle these intractable ores, this being the obstacle on which hundreds of, what would otherwise have proved prosperous enterprises, have been wrecked. We have said this much by way of showing the important bearing that any improvement in the treatment of our obstinate ores must have on the mining industries of this coast.

The Contriver and His Contrivance—Getting to Work.

The process we are about to describe is the invention of Dr. John Campbell, of New York city, who had the patentable features of it secured by letters patent two years ago. Since that date a good deal of time has been spent by him and his assistants in perfecting the manipulations and appliances of the method and testing its merits in a practical way. Hence, the delay in announcing this new device to the public, the inventor being unwilling that it should attain any notoriety until he had corrected some minor defects and rendered the whole as perfect as possible. To the performance of this task Dr. Campbell brought large scientific acquirements and experience in the treatment of difficult ores, insuring to him the advantages that result from theory and practice combined. From the knowledge so obtained, this student and worker has evolved the plan about to be described for working non-amalgamating and non-smelting ores. Owing to the natural and very proper distrust with which all new methods are apt to be regarded at first, some difficulty was for a time experienced in getting enough ore to keep the works steadily employed, this affording further cause for interruptions and delays.

Apparatus and Various Manipulations.
The Campbell process is operated on this

coast by the Pacific Mining and Reducing Co., who have their works in this city, at No. 410 Ritch street, the site being in close proximity to the freight depot of the Central Pacific and the Southern Pacific railroad companies. In the building which contains the plant, a plain but spacious and commodious structure, has been concentrated everything pertaining to the business. Here are the roasting furnace, condensing chambers, lead bath, smelter, etc. Entering the building from Ritch street, the visitor passes through a large apartment filled with sacks and piles of ore to the rear, where are situated a Dodge rock breaker and a Dodge pulverizer, which crush the ore sufficiently fine to pass through a twenty mesh screen. Near by are located the boiler and engine, the latter having ample power for driving all the machinery connected with the establishment. The ore after being crushed to the above fineness is passed through a hopper to an elevator, which carries it up and discharges it into a funnel at the top of the roasting furnace, a stack six feet in diameter and twenty-four feet high, made of heavy boiler iron and lined with fire-brick. As the ore from the funnel dropping by its own weight enters the furnace it is struck by a steam exhaust, which imparts to it a rotary motion, causing it to spread out evenly and fill the interior of the tube.

Two apertures at the bottom of the furnace, on opposite sides, are entered, each by an iron nozzle, through which is kept up a constant flow of

Crude Petroleum.

Being fired by the contrivance known as the Parson & Northey hydro-carbon injector, the flame from the burning fluid is driven into and up the furnace, creating an intense heat. The falling ore, retarded in its descent by its swirling motion and the upward current of hot air, is subjected to a thorough roasting before it reaches the pit prepared for its reception at the bottom of the furnace. This petroleum, kept in a large cask elevated above and at some distance from the furnace, to which it is fed through a connecting pipe, proves to be a cheap and otherwise serviceable fuel, costing but six cents per gallon, from four to six gallons sufficing, on an average, to roast one ton of ore. When once the furnace is brought to a high temperature, not over two or three gallons of oil are required for roasting ores that carry a large percentage of sulphur, as that mineral, when heated to the point of combustion, becomes itself a fuel, greatly assisting to feed the flames.

The smoke, fumes and dust from the roasting furnace are taken in on the overturn and carried down into and through a series of

Condensing Chambers.

Five in number, after passing along which the residue escapes through the main smoke stack. The last chamber in this series is partially filled with water, which absorbs any noxious gases coming in contact with it. The dust collected and the vapors condensed in these chambers contains always more or less gold and silver of atomic fineness, a considerable saving of the precious metals being effected through their employment. The arrest of these gases, fumes and smoke in this manner, besides the gain mentioned, serves to relieve the premises from what might otherwise prove a source of ill health and discomfort.

The ore, which in its passage through the flames becomes almost wholly desulphurized, drops into a brick inclosure beneath the furnace, whence it is hauled out on a cooling floor. Here such amount of iron as may be necessary for fluxing is added, after which it is removed to another apartment containing

The Lead Bath and Plunger.

The most novel, as well as noticeable feature of the new process, and which may be described as an oblong-nearly rectangular iron vessel, or receiver, inclosed on all sides and capable of containing 4,000 pounds gallons or more of melted lead. Projecting upwards from one side of this vessel, near the bottom, is an iron pipe ten inches in diameter and open at the top. This vessel stands over an oven, which being heated with charcoal brings its contents up to the proper temperature, and so maintains them while work is going on. From one and a half to two tons of lead having been placed in the bath, or receiver, fire is applied in the oven beneath and the metal brought into a molten state. This done, a quantity of ore is thrown into the iron pipe, and by means of a pestle-

shaped plunger that works up and down in the latter, is forced through the mass of molten lead, the greater buoyancy of the ore bringing it speedily to the surface. In its passage through the lead the ore takes on from thirty to forty per cent of that metal. Coming on top and there remaining, the dry ore so mixed mechanically with lead is taken up on a shovel and removed from the bath through an opening on its upper side. Thrown in a heap, the heated mass is cooled with a spray of water, after which it is weighed and passed into the smelter, the quantity of lime required for fluxing, determined also by weighing, having previously been added. Charging the ore in this manner with lead converts an otherwise non-smelting into a smelting ore, in which condition it readily takes up the silver and gold. The lead is not here used instead of quicksilver for amalgamating the precious metals, but as an agent for promoting smelting.

The Smelter Here in Use

Is a water jacket furnace of about twenty tons daily capacity—fuel, English selected or patent prepared coke, though it is thought a mixture of this with common gas coke could be used to advantage. In localities where coke could not

grade and thereby save cost in transportation and refining. As this procedure can be carried on indefinitely, it is possible to enrich the bullion to almost any desired degree, it being the practice of the company to run it up to a value of about \$3,000 per ton. In districts far removed from railroads or other cheap means of transportation it might be found economical to grade the bullion up to five or even ten times this value. The loss of lead is inconsiderable, amounting to not more than four or five percent to the ton of ore treated, such loss varying with the conditions of the ore and furnace. Eventually a good deal of the lead so temporarily disappearing is recovered.

Recapitulating the Strong Points.

As this process has now passed through its experimental stages, during which it was subjected to the most crucial tests, some of which suggested important alterations and amendments, it is possible to speak of the results reached by it with a good degree of confidence. Summarizing what seem to be its more patent advantages, as explained by the managers, the following points are presented:

1st. The item of cheapness; the managers stating that ores of the most base and obstinate

ing too little lead for smelting, and too much for amalgamation.

4th. Uniformity and certainty of results: Be the ores what they may, the outcome of the Campbell process varies but little. The ore to be reduced having been carefully sampled and assayed the product can be estimated with great closeness beforehand.

5th. Simplicity: As this process is without eccentricities, so are its manipulations few and easily understood. Any good assayer or practical metallurgist can master all there is about it in a very short time, care and skill rather than great scientific knowledge being essential on the part of those charged with the general supervision of the business. A point requiring much care is the addition of the proper fluxes, to ascertain which, frequent assays of the ore become necessary.

The Campbell process has been examined and its workings witnessed by a number of our leading mine owners, millmen and metallurgists, who regard it with favor. The course pursued by Dr. Campbell of quietly going on and perfecting his process, instead of seeking to prematurely advertise its merits, as has been too much the practice with this class of inventors, is one to be commended. Besides the establishment in this city, similar works have been put up and are now ready for operations at Idaho Springs, in the State of Colorado, the prospect being that many others will soon be erected at different points throughout our mining States and Territories.

The general office of the Pacific Mining and Reducing Company is at 413 California street, San Francisco; officers John D. La Monte, President; James W. Burling, Secretary; John Campbell, General Manager; George F. Beardsley, Assayer and Metallurgist.

A New Barley Crusher.

We give an engraving on this page, of a new barley crusher, now offered to the public by the inventors and manufacturers, Best and Althouse, of 614 Broadway, Oakland. This crusher is constructed on new principles and is different from any other grinding machine now in use. It has an iron frame, weighs 1500 pounds, and has three rolls; one nine inches in diameter, and two rolls, each five inches in diameter. The two small rolls work against the large one, and grain passes through between two sets of rolls and is crushed by gradual reduction. All the rolls have an end movement, and this end movement causes the faces of the rolls to be always moving when crushing. Thus the machine combines four principles of grinding, while there are but two used in the ordinary roll system of grinding, viz: The crushing and the differential motion of the rolls. The two new features that have never been used before, are: First.—the grain passes through two sets of rolls. Second.—the end movement of rolls.

The inventors assure us that this machine can be attached to the engine of a thrashing machine in the field and grind the grain as it is thrashed, at the rate of fifty barrels of flour per day; or at the same time it can chop from forty to fifty tons of barley. They guarantee this machine to be superior to the best buhrs or rolls manufactured, and that it will do double the amount of work that the best make of French buhrs will do. It does not require half the power they use. It makes No. 1 Graham flour. The rolls never get dull or want sharpening.

A profitable mine yields more business and more comforts to the surrounding region than anything else can. It makes work for miners, lumbermen, wood and coal and iron men; the merchant and the farmer alike rejoice at it, and the more it produces the more prosperous every other business is, for it makes work and it absorbs materials as nothing else does, and the greater its production the greater is the demand for earth's necessities and luxuries.

"When a mining claim is abandoned subsequent to publication and period to entry and payment, a case should be presented in which the executive department should be compelled to take jurisdiction, because the law under the state of facts allows the abandoned land to be again located by any qualified person in the same manner as if no location of the same had been made and makes no provision for the determination elsewhere of any question or controversy arising out of this class of conflicting claims."

"The fact that large expenditures have been at some prior period made upon a mining claim does not excuse the claimant from the necessity of complying with the law in making annual improvements or performing annual labor."

VICTORIA and the other Australasian colonies urge the British Government to annex the New Hebrides, the Solomon Islands and other groups of islands in the Pacific.

A PERMANENT restoration of exhausted and worn-out functions follow the use of Brown's Iron Bitters.

THE BEST & ALTHOUSE BARLEY CRUSHER.

well be obtained charcoal might, of course, be made to answer for fuel. A large iron pipe receiving the smoke, dust and fumes from the smelter carries them over and discharges them into the line of condensers connected with the desulphurizing furnace, thereby making these arrangements for avoiding waste and rendering innocuous what would otherwise become a standing nuisance, very complete. The bottom of this smelter forms a huge crucible, into which the molten bullion settling is there retained at a fixed level, with the slag on top. This bullion, under such arrangement, flows out in a small but constant stream into an iron kettle, whence it is dipped into molds, forming pigs of about eighty pounds each. The slag, as often as there may be occasion, is drawn off and run into conical-shaped iron pots. It contains never any appreciable quantity of gold or silver, the most careful assay failing to detect in it more than a trace of either. Any copper that it contains is recovered in the shape of a button at the apex of the cone, from which it can readily be detached with a hammer.

Another Noteworthy Peculiarity

Of the Campbell process consists in the plan of returning this lead bullion and passing it repeatedly through the lead bath and smelter every time in connection with a fresh batch of ore, each of which imparts to it an additional quantity of the precious metals, the object of this being to bring the bullion up to a high

kind may be worked by the method described, at the average cost of less than \$8 per ton.

2d. Effectiveness. We are told that the precious metals contained in any ore, however refractory, may be extracted to within three or four per cent of results obtained by fire assay, and generally somewhat closer. As evidence of its capabilities in this respect, it may be stated that the works of the company are now and for some time past have been running on ore from the Manzanita Mine, situated on the easterly slope of the Coast Range, in Colusa county. This ore, as rebellious, perhaps, as any in nature, and which had been given up as wholly intractable, after trial by the Swansey, Newark, Selby and other first-class metallurgical establishments, seems to surrender its gold under the Campbell process, with the greatest readiness. As this ore carries, on an average, gold to the value of \$60 per ton, it can be reduced at these works with large profit, the cost of mining, transportation and treatment amounting to less than \$12 per ton. The Manzanita mine is said to contain a large body of this high grade but exceedingly obstinate ore. Lots of ore from other mines, distinguished for their baseness, have shown themselves docile when treated by this process.

3d. Adaptability to the treatment of a large school of ores incapable of being successfully handled by other methods, such as ores carry-

Metallurgy and Ores.

Nevada Metallurgical Works,

No. 23 STEVENSON STREET,
Near First and Market Streets, S. F.
ESTABLISHED, 1869. C. A. LUCKHARDT, Manager.

Ores Worked by any Process.
Ores Sampled.
Assaying in all its Branches.
Analyses of Ores, Minerals, Waters, Etc.
Working Tests (Practical) Made.
Plans and Specifications furnished for the most suitable process for working Ores.
Special attention paid to Examinations of Mines, plans and reports furnished.

IMPORTERS OF AND DEALERS IN

Assayers' Materials, MINE and MILL SUPPLIES,

CHEMICAL APPARATUS AND CHEMICALS, DRUG-
GISTS' GLASSWARE AND SUNDRIES, Etc.

118 and 120 Market Street, and 15 and 17
California St., San Francisco.

We would call the attention of Assayers, Chemists,
Mining Companies, Milling Companies, Prospectors, etc.,
to our full stock of Balances, Furnaces, Muffles, Crucibles,
Scorifiers, etc., including, also, a full stock of
Chemicals.

Having been engaged in furnishing these supplies since
the first discovery of mines on the Pacific Coast, we feel
confident from our experience we can well suit the demand
for these goods both as to quality and price. Our
New Illustrated Catalogue, with prices, will be sent on
application.

Our Gold and Silver Tables, showing the value per
ounce Troy at different degrees of fineness, and valuable
tables for computation of assays in grains and grammes,
will be sent free upon application. Agents for the Patent
Plumbago Crucible Co., London, England.

Quartz Mill Screens, and Per-
forated Sheet Metals of every
description. I would call special
attention to my SLOT CUT and
SLOT PUNCHED SCREENS,
which are attracting much at-
tention and giving universal
satisfaction. This is the only
establishment on the coast de-
voted exclusively to the manu-
facture of Screens. Mill owners using Battery Screens exten-
sively can contract for large supplies at favorable rates.
Orders solicited and promptly attended to.
32 Fremont Street, San Francisco.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved, White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 0x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Holsts for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 0x10 to 30x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

CONTINENTAL WORKS, BROOKLYN, N. Y.**Duc's Mechanical Atomizer or Pulverizer.**

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL, OCHRE, MANGANESE, IRON ORES,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanics in design and of first-class construction. Weight 5,500 lbs.; heaviest pieces, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

THOS. F. ROWLAND, Sole Man'fr. Brooklyn, N. Y.

JOHN TAYLOR & CO.

118 & 120 Market and 15 & 17 California St., San Francisco

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First St., a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. Reference as to above can be had upon applying to this office.

WIND MILL. One of the best made in this State for sale cheap on easy terms. Address, W. T., care of Dewey & Co., S. F.

HYDRAULIC GRAVEL ELEVATORS,

For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY.

No. 51 Fremont Street, Office of the Hydraulic Gravel Elevating Mining Co., S. F.

**William Hawkins.**

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in Dewey & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR WEEK ENDING JUNE 5, 1883.

278,675.—AGRICULTURAL MACHINE.—John Bachelder, Napa, Cal.
278,890.—FRUIT DRIER.—C. A. Curran, Albany, Oregon.

278,996.—MACHINE FOR WETTING GRAIN.—John Miller, Milton, Oregon.
278,225.—GANG AND SULKY PLOW.—Phillip Moore, Portland, Oregon.

279,012.—FEEDING STRAW AS FUEL TO FURNACES.—W. S. Prosser, Auburn, Cal.

279,031.—CRAVAT SUPPORTER.—Frederick Smiley, S. F.

278,836.—TIRE UPSETTER.—William Valentine, Redding, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

TUCKER ATTACHMENT FOR SEWING MACHINES.—Alfred A. Fisher and Albert Hart, S. F. No. 278,422. Dated May 29, 1883. The improvements consist generally in the arrangement of parts and their construction, having in view the provision of a tucker attachment more nearly approaching perfection than the machine previously patented for the same purpose by these inventors. They consist particularly in a novel means of adjusting the base plate and the lower or under guard, and in the particular construction of said guard and its under-lying tuck securing plate; also in a novel means for regulating the width of the tuck guiding slot and in a novel adjustable tuck guard or support within the slot; also in a novel means for adjusting the upper guard, and in adjustable attachments thereto for guiding the goods to the tucker, and in the means by which this is accomplished.

ADJUSTABLE COUPLING FOR HARNESS.—Louis Wartenberg, Anaheim, Los Angeles county. No. 274,474. Dated May 29, 1883. This adjusting coupling for harness is specially adapted for the links or connections by which the tug is attached to the whiffletree. It consists of a screw turning in a nut in the link, to which the end of the screw is secured, said screw having a swivel connected with its opposite end, to which the coupling hook or bar is connected.

CRAVAT SUPPORTER.—Frederick Smiley, S. F. No. 279,031. Dated June 5, 1883. This invention relates to a new and useful cravat supporter, the object of which is to conveniently and effectively secure the cravat to the collar button. The invention consists in a metal loop hinged to the lower back edge of the stiffener, and having certain spring wires within and guarded by it, to form with its head a means for grasping the shank of the button.

TIRE UPSETTER.—Wm. Valentine, Redding, Shasta Co., Cal. No. 278,836. Dated June 5, 1883. This invention relates to a new and useful tire upsetter, and it consists in a stationary block having a fixed and a movable jaw, and sliding block having similar jaws, though oppositely placed, and an intervening lever so connected with the movable jaws that by its movement in one direction it separates the sliding from the stationary block after swinging open the movable jaws, and by its movement in the reverse direction it draws the sliding block with its jaws, the stationary block having previously closed the movable jaws. The object of this invention is, broadly, to shrink, or, as it is commonly called, "upset" tires. This is a well known operation, consisting in gripping the tire in two places and forcing the gripping devices together, whereby the tire is thickened, and consequently shortened to render it smaller in diameter. The particular object of this invention is to provide a convenient and effective device for this purpose, one in which the entire operation of gripping the tire and shrinking it is performed by the movement of a single lever.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

H. W. McCREW—Santa Clara county.
M. C. OWEN—Santa Cruz county.
J. A. WRIGHT—Merced, Tulare and Kern counties.
JARED C. HOLE—California.
B. W. CROWELL—Arizona Territory.
N. H. HARRISON—Plumas county.
M. H. JOSEPH—Fresno, Nev.
I. M. LINDY—Los Angeles, San Bernardino and San Diego counties.
A. C. KNOX—Oregon and Washington Ter.
F. W. STRATTON—Sierra and Yuba counties.
J. J. BARTHALE—Yolo county.
JAMES W. BOYER—Sacramento county.

At Sweetwater the Summers mine has 30 men at work.

Wrought Iron Pulleys.

There is now in this city an establishment for the manufacture of wrought iron pulleys, where they have just completed the largest wrought iron pulley ever made. It is ninety-six inches in diameter with fifty inch face. It was made for Starr's mill, Vallejo, for which they have already manufactured 500 similar pulleys of smaller diameter. Messrs. Clot & Meese, of the Reliance Machine Works, 129 and 131 Fremont street, who make these Medart patent pulleys on this coast, have facilities for making fifty pulleys a day. They have shown commendable enterprise in acquiring the right for this patent of the coast, and are reaping their reward. They supply the machine shops of this city. They have a contract now on hand to supply the large flour mill, about to be erected in Portland, Oregon, with over 900 pulleys of various sizes.

The objections to cast pulleys in common use, are, that they are apt to be badly balanced and unduly heavy and weak. In casting such pulleys the rim chills in advance of the center, which causes the parts to be strained and weakened, and the rim is liable to be weakened. The wrought rim pulleys combine the minimum weight and the maximum strength. The arms of the pulley are straight, and their number is increased. The smaller sizes have six, the medium eight, and the larger ten or twelve arms. The rim, owing to the nature of the material, is much stronger than the cast rim. The construction is such that this style of pulley is well balanced for all speeds. The center of gravity of a completed pulley, made by this process, is made to coincide more absolutely with its geometrical center than has been possible under the ordinary methods of manufacture. The wrought iron face is denser than the cast, and being ground smooth it greatly lessens the wear on belting. There is no danger of breakage in handling when shipped loose, which saves freight. The rims are cold rolled, either crowning or straight. The process of manufacture, as well as the product and machinery, are protected by patents.

Government Bullion Statistics.

Although only a very brief abstract of the report of the Director of the Mint has been telegraphed to this coast, there is great dissatisfaction at the figures of bullion product referring to this State. The yield is given as a total several millions below that which Mr. Valentine, of Wells, Fargo & Co.'s Express, has assigned California, and his figures have always been considered reliable. If Mr. Burchard is reported correctly he has made a very bad blunder in Nevada county figures. He places that county's yield at some \$360,000. The fact is that the Idaho mine alone yielded \$566,000, and paid \$263,500 in dividends. The North Bloomfield mine yielded \$386,146, and the Milton, \$416,044. These mines foot up alone a million and a quarter. It seems likely from this that the director is misrepresented by the telegraphed figures, as it does not seem possible such a stupid blunder could be made.

Still, what are we to say of Sierra county, as referred to in the following paragraph from the *Sierra Tribune*: "Director Burchard, of the Mint, estimates the production of Sierra county during that time at \$110,000! This is about as near right as the Mint statistics generally are. The gold production of the Rainbow Mine alone last year was about \$200,000, and the Sierra Buttes yielded at least \$100,000. The total production of the county for 1882 was probably at least \$500,000."

It is apparent that the statistics of production are placed too low here at any rate. The truth of the matter is that the Mint Director's Bureau has more of a political flavor about it than is good for the results. When men who collect the material for the chiefs' report are selected for political reasons rather than for special fitness, good work cannot be expected.

The publication of erroneous statistics is much worse than no publication at all. People always read these reports as "blue books" and base their opinions on them. When California is credited with twenty-five per cent less than the real yield, corresponding injury is done to her mineral resources. If the Government is going to give us statistics, it ought to have them properly collected and have them correct. The figures as published, do California great injustice.

Rogers' District, Arizona.

[Written for the PRESS by C. H. AARON.]

Northward, a little easterly from Pinal, over rolling foothills formed of conglomerate and covered with the gravelly detritus thereof, consisting largely of quartz, along a dry wash cut through the same conglomerate, over a low ridge and into a large canyon, the bed of which for some distance consists of a hard blue rock, thickly veined with adherent barren white quartz, up "a very high hill" at its head, in which mica, schist and barren quartz abound, over the crest and along a ridge of coarse porphyritic granite, covered with "brush" and Spanish daggers, and intersected by a prominent but said to be a barren quartz ledge, down again into a pretty canyon well wooded with oak and juniper, with plenty of grass, but at this season no running water, brings the traveler to the camp at Rogers' district.

The camp consists of three rough shanties, a tent or two, and a small smelting furnace, built in Mexican style of adobes. A rudely constructed horse power machine works the blower. The mines are to the left, looking northward, in a continuation of the ridge spoken of which divides the watersheds of the Gila and Salt rivers. The formation here is syenite chiefly. The veins are small and well defined, carrying rich ore in lumps and bunches among a mass of vein matter. Silver glauconite, antimonial galena, lead carbonate, azurite and malachite, copper arsenate, pyrites, ochreous matter of various shades, anglesites or, as the miners called it, "anthracite of lead," quartz and calcite are among the contained minerals. A good deal is said about "chlorides" but none was observed. The miners usually call any oxidized or ochreous ores "chloride ores," while the true silver chloride is known among them as horn silver only.

The principal mines were discovered seven years ago, and they have been worked to a trifling extent ever since. A few carloads of selected ore have been exported, but the expense consumed the greater part of the proceeds. Some working mechanics from Pinal have recently put up the little smelter, which is now just beginning to turn out bullion. As the ore is well adapted to smelting, it is hoped that the miners, who have shown great pluck and perseverance, will now be enabled to demonstrate the value of their properties, which is only open to question on the score of continuity of the veins and quantity of ore, the quality being quite satisfactory.

The district is well wooded and fairly watered. The timber is chiefly oak and juniper quite near the mines, but at the distance of about two miles is a pinery, from which an abundance of lumber and nine timbers can be got in the future, should the requirements of the camp justify the erection of a sawmill. The eastern slopes in particular are covered with a dense growth of brush, which makes prospecting difficult. Of course cactus is not wanting, and Spanish daggers bristle on all sides. In the canyons, locust, walnuts and cherries grow; the soil in many spots being rich and deep. The manzanita reminds one of California, and accounts for the alleged presence of bears, while deer, rabbits and quails abound. Peccaries are also found, if not here at least a few miles away.

Rogers' district is fifteen miles from Pinal by the route described. A better entrance to and exit from the district can be had to the westward, over a comparatively low pass leading to a canyon which debouches at a point on the Casa Grande road, only forty-five miles from the railroad; and this will be the route should the camps flourish. It passes through Cole district, in which are some very promising prospects.

It is very fortunate for the miners in this section that a rather high mountain intervenes between it and Pinal, otherwise the purveyors of wood to the Silver King mills would soon make that commodity very scarce here. As it is, they have nearly reached the summit on the southern side, and may possibly yet cross over under the stimulus of enhancing value, as any desired grade can be had by means of winding trails over which a train of "burros" can pass.

On one of the mountains bordering the little valley of Rogers' district on the east, are said to be some ruins of ancient dwellings. The miners wonder what could have induced the residence in such a place, of a people who knew enough to build such houses, and did not know enough to dig for silver. It is suggested that game and wild fruit may have been the object.

DESTRUCTIVE FUNGUS.—Dr. H. W. Harkness, of the California Academy of Sciences, furnishes us with the following note: "The fungus which has so generally affected the leaves of the apricot and cherry is the *Phyllosticta circumscissus* (Cook). The fungus destroys a limited portion of the leaf, which it attacks when the dead part shrinks away from the living, and tearing itself loose from the healthy portion of the leaf, falls to the ground; hence the holes. In South Australia, where it abounds, it is called the 'shot hole fungus.'"

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walked with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

Enlarged Issues of the Mining and Scientific Press.

It is the intention of the publishers of this journal to spare no enterprise in advancing the future interests of its readers by all reasonable and practicable methods. Among other advances, we contemplate issuing soon several extra sized sheets, especially devoted to different important localities, commencing with the

Territory of Alaska.

The contents of this issue will include a well prepared map nearly the size of two pages of the PRESS; views of several seaports, towns, scenery and other objects of interest. This is a new land, concerning which new information is coming to hand, and its resources are just being developed. Alaska is situated on our own coast, largely drawing her supplies from our own State, and will soon become of that importance to our community which will render it to our advantage to be well posted on all that pertains to the welfare and progress of our neighboring northmen. Our map will show the numerous water courses of Alaska, the means of water communication, the harbors, etc. We shall give a description of all the mining regions so far opened, and in fact such information as is available, and will be of general interest.

Other double editions will follow shortly after, which will be devoted to the special interests of other mining localities.

All these regions possess more or less interest for California and San Francisco. We ship goods of certain kinds from here, and, from a commercial point of view alone, our interests are mutual. Moreover, the advancement of these regions does good to the whole coast, in which we are all interested.

Persons who can contribute information of special or general interest to our readers for these various issues are solicited to send the same as early as possible. If miners will send us descriptions of their mines or camps we shall be very glad to receive them.

As we make this extra effort to advance the interests of all concerned in the places named, we ask that all who can, to favor our enterprise by making the matters more widely known, and the MINING AND SCIENTIFIC PRESS more extensively patronized. The mining literature of the world is comparatively limited. Miners and scientific men especially should be liberal to assist their helpers in a line of publication, which, at best, cannot be expected to be largely profitable while doing strict justice to the highest interests it represents.

The dates of issue of the proposed extra sheets may be varied, if circumstances should demand it, but due notice will be given.

FURNACE.—We had a call this week from Mr. Robert A. Nevin, of Silver Cliff, Colorado, the patentee of a valuable ore-roasting and chloridizing furnace. Mr. Nevin states that it has been in use at Navajo mine, in Tascara district, Nevada, and has resulted in a large saving to the Navajo. Mr. Nevin thinks of instituting suit for the infringement of his patent, unless a satisfactory settlement can be effected.

SECRETARY CHANDLER will advertise for sealed proposals for the purchase of two iron-clads, two iron and twenty-six wooden ships, which have been condemned by boards of inspectors as unfit for naval service. The following vessels now at Mare Island are included in the list: Benicia, Narragansett, Nyack, Saco, Tascara and Alaska.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times,) by turning a leaf.

Recent Contributions to the California State Mining Bureau.

Double Rates of Interest.

The following is a synopsis of the decision rendered by Judge Marks against double rates of interest charged on a mortgage note in the case of Oakland Bank of Savings vs. John Applegarth:

This action is brought by the plaintiff to foreclose a mortgage, made by the defendant to the plaintiff the 20th day of November, 1879, the security of a note for \$6,000, bearing interest at the rate of one and one-tenth per cent. per month, payable monthly in advance, and setting forth that in case of default of these payments, shall bear interest from the date of maturity at two per cent per month, compounding monthly, and shall then, at the option of the holder, become payable. The sum so due shall thereafter bear interest at the rate of two per cent per month, compounding monthly until paid.

The direct issues made by the pleadings and the main question before the Court are: 1st. What was the amount due the mortgage debt at the commencement of the action? 2d. Was the sum due plaintiff on the contract?

The opinion of the Court is that it cannot influence the latter contract and that Sec. 1,919 of the Civil Code places an express limitation on such contract. The Supreme Court, in bank, recently decided in the case of the Savings & Loan Society vs. Horton, that a claim charging the original rate of interest at the election of the security holders, was within the limit of Sec. 1,919 of the Civil Code, and consequently inoperative. It appears to the Court that the amount due plaintiff from defendant on the contract, on the 1st day of September, 1882, was \$6,383.29, less the amount to be legally deducted therefrom by defendant, as the mortgage tax on plaintiff's mortgage for the current year. That the defendant tendered the plaintiff the sum of \$6,344.55, which the plaintiff refused to accept, without any valid reason. The Court considers that Sec. 2,076 of the Civil Code of Procedure is conclusive as to the consequence of an unqualified refusal and which estoppes the plaintiff from taking anything from the defendant by virtue of action to foreclose the mortgage. According to these views, the Court on an examination of the law and evidence, it follows that the defendant is entitled to the equitable reposition of the Court, and is of opinion that relief awarded to the plaintiff should be substantially as recited by the defendant in his answer, that the same is true and the defendant is entitled to recover cost of this action. The tender of defendant on September 1st, of the full amount due, stopped the interest on the obligation.

The Court, holding from the evidence adduced and the law applicable, that the defendant is entitled to receive the sum of \$82.62, and the plaintiff the remainder of the money held by the Court in this action. Defendant is also entitled to a judgment in his favor for costs of this action.

Alpine's Mines.

Several mines have been worked during the past year in the county and some little prospecting done on what was considered favorable locations, with very encouraging results in some of the claims. The recent prospects struck leads us to believe that there yet remain rich mines within our border undeveloped, and that our county is not played out as a mining field as asserted by many. Our county labors under great disadvantages as against several other mining counties adjoining us. There seems to be a decided prejudice against Alpine by many, as a mining district, for the reason that so many have been deceived and defrauded by those doing a mining business in the county. They have passed judgment on our mining industries, without ever enquiring what was the cause of the failures. In the first place expenditures have been made on the surface, instead of opening up the mines, and a large staff of hangers-on have eaten up the funds of the stockholders, or used it in such a way as not to open up and develop a mine as it should be, or in useless and extravagant expenditures, and Alpine is blamed for her valueless mines. The time is not far distant in the future when capitalists may visit our section in search of, and to purchase mines. We want no booms. Open up your mining properties instead of trying to sell undeveloped claims for fancy prices; when purchasers come along be reasonable and willing to sell for the actual value of your mine, and not its prospective value. The time has passed for fancy prices, and the amount in sight as in other kinds of business, is the true value of mining properties. —Monitor-Aquas.

News in Brief.

The British underwriters are demanding additional premiums on vessels going to China, especially Frenchmen. The increase of piracy is feared.

A SOVEREIGN insurance policy has just been taken by a merchant of Huron, viz: The company insures the windows against cyclones, the risk being \$125.

The Chinese excursion and picnic to Coney Island, on Monday, was attended by 250 Chinese, chiefly members of the different Sunday schools.

In 1860 the population of Oakland to San Francisco represented a ratio of one to thirty-seven; in 1870, one to fifteen; in 1878, one to eight, and by the school census of 1883, one to six.

CAPTAIN EADS will sail for Europe on the 20th on business appertaining to the Tehuantepec Ship Railway. Captain Eads asserts confidently that at the end of five years ships will be carried on rails from one sea to the other.

At Hamburg a number of prominent shipping firms expressed sympathy with the prospect of a second Suez canal, and resolved to communicate with the British Committee with a view of eventual participation in the undertaking.

The track of the Northern Pacific railroad will be laid to Helena, Montana, in a few days, and the first through ticket from Helena and Butte to St. Paul will be sold to the highest bidder at auction. A lively competition is expected for the honor.

A DISPATCH from Dallas, Texas, says the cattle drive so far this season exceeds all expectations, as over 200,000 head have already passed over the trail that leads through Albany. This does not include more than half the cattle that have been driven from Texas.

REV. EDWARD EVERETT HALE proposes writing a history of the Pacific ocean and its shores. He has been collecting material for the work for forty years past. He will write a chapter on the discovery of California for the forthcoming history of the United States.

A TRUE friend to the weak and convalescent is Brown's Iron Bitters.

And in accordance with law, and an order of the Board of Directors, made on the 10th day of April, 1883, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at 528 California St., Room 6, San Francisco, Cal., on TUESDAY, the 5th day of June, 1883, at the hour of 1 o'clock p. m., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expense of sale.

A. MARTIN, Secretary.

OFFICE—Room 6, 528 California St., San Francisco California.

POSTPONEMENT.

The above sale of delinquent stock is hereby postponed to THURSDAY, the 28th day of June, 1883, at 1 o'clock p. m., at the same place. By order of the Board of Directors.

A. MARTIN, Secretary.

San Francisco, June 6, 1883.

DIVIDEND NOTICE.

OFFICE OF THE

Silver King Mining Company.

San Francisco, June 4, 1883.

At a meeting of the Board of Directors of the above named company, held this day, a Dividend (No. 42) of twenty-five cents (25c) per share was declared, payable on FRIDAY, June 15, 1883, at the office of the company, room 19, No. 328 Montgomery Street, San Francisco, Cal. Transfer books will close June 9, 1883, at 3 p. m.

JOSEPH NASBI, Secretary.

MINING PARTNER WANTED.

A gentleman who is a graduate of Freiberg and has had experience in the mines on this coast, is desirous of forming a partnership with some one experienced in mining affairs, with a view to establishing works here. Having some capital he wishes to add it to what may be furnished by the partner, with the idea of forming a permanent mining and metallurgical business. A graduate of some mining school preferred.

Address "B. S."

Care of Editor "Mining and Scientific Press,"

252 Market St., San Francisco, Cal.

DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company.

San Francisco, June 2, 1883.

At a meeting of the Board of Directors of the above named company held this day, Dividend No. 55, of twenty-five cents (25c) per share, was declared, payable TUESDAY, June 12, 1883, at the Farmers' Loan and Trust Company, in New York, or at the office in this city.

WILLIAM WILLIS, Secretary.
OFFICE—Room No. 29, Nevada Block, No. 300 Montgomery Street, San Francisco, Cal.

Patent Life-Saving Respirator.

PREVENTS LEAD POISONING AND SALIVATION.

Invaluable to those engaged in dry crushing quartz mills, quicksilver mines, white lead corroding, feeding thrashing machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and, if not satisfactory, the price will be refunded. Price, \$3 each, or \$30 per dozen. Address all communications and orders to

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

PARKE & LACY, General Agents, 21 & 23 Fremont St., S. F.

EXCELSIOR BLASTING POWDER,

Manufactured by the

EXCELSIOR POWDER COMPANY.

This is no new, patent, non-explosive Safety Powder, but the Genuine Standard Nitro-Glycerine Powder, as safe to use and handle as any other Nitro-Glycerine Powder manufactured. The fumes and gases, common in nitro-glycerine powders, are destroyed, and do not leave the miner with headache or nausea.

The powder is put up in cartridges of any size to suit the consumer, and is exploded in the same manner as all other high explosives; that is, by means of cap and fuse, or by electricity. It is not claimed for this powder that it is a non-explosive, or safer than other nitro-glycerine powder. All powder, and especially nitro-glycerine powder, should be handled carefully. The EXCELSIOR POWDER is as safe, and for strength far surpasses any other powder on the market. Address all orders to

EXCELSIOR POWDER COMPANY,

Mining Machinery Depot, **PARKE & LACY,** 21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Educational.

Number 25.

Timbering in Mines.—No. 14.

Special Form of Timbering.

A form of timbering is employed in France and described by Audre, that is deserving of special attention, inasmuch as it possesses very valuable qualities and is but little known in other countries. This form is capable of offering an enormous resistance; so great, indeed, as frequently to withstand the pressure when the walling has been completely crushed. It has been found to last three or four years in situations where the ordinary timbering has been destroyed in two or three months, and to have successfully resisted the destructive action of the "creep," when, in consequence of an accident or a strike, the mine has been closed for some time. These properties render the former valuable for the main roadways of a mine, and for use on those parts where the pressure is very great. As a suitable substitute for walling, the former offers, under such conditions, a very considerable degree of economy.

The two main features of this system are, first, the employment of struts to support the stanchions and the cap at the points where they have a tendency to yield; and, second, the use of longitudinal pieces to bind together the different sets of timbering.

The system will be understood from an inspection of the accompanying drawings, Fig. 1 of which represents a set as designed for a narrow roadway of a single line of rails. Fig. 2 is a sectional or side view. The principal timbering observed is of the ordinary construction, the peculiarity of the system lying wholly in the means employed to strengthen the structure. The timber used for the purpose is round, and of relatively small dimensions, the diameter being about three inches for narrow roadways, and about four inches for the ways intended for a double line of rails. It will be seen from the drawings that two uprights are placed inside the principal stanchions, and in contact with the latter throughout their length. These uprights are firmly set in the floor, and reach to about one-third of the height of the stanchions. Their upper ends are bird-mouthed, to receive the longitudinals, which are intended to bind the sets together. These longitudinals are merely placed end to end, and they are held in position by friction alone, no nails or other means of connection being used. The length of these pieces will be equal to the distance of the sets apart, center to center, or some multiple of that distance, and it is important that they all be of the same diameter. The distance of the sets, that is, each pair of stanchions with their cap, apart, is determined, of course, by the strength of the rock. Generally, in fairly strong rock, they may be placed at intervals of three feet from center to center, and in very weak and fissured rock at intervals of eighteen inches. In some cases it may be necessary to place them closer together. As it is impossible to estimate the strength of rock accurately, it may also become necessary to double the sets, that is, to place a new set between every two existing sets, after the first timbering has been completed. The dimensions of the pieces will likewise be determined by the same condition of strength in the rock. As the pieces furnished are rarely of equal size, the larger and small should be made to alternate so as to have the weaker set be-

tween two stronger ones. In some cases, economy of timber may be gained by thus alternating sets of different dimensions. It is desirable that the timber should be sent into the mine cut to the requisite length.

The similar longitudinal is placed in the middle of the cap, and supported by two struts abutting upon the longitudinals. The ends of these struts are bird-mouthed, like the upper ends of the uprights. Thus it will be seen that the stanchions and cap of the principal timbering are supported at those points at which they begin to yield, and that in consequence of the connection furnished by the longitudinals, a pressure occurring at one point is distributed over several sets of timbers. Thus the timber

is produced, capable of resisting an enormous pressure. It is obvious that this bracing may be applied to every set of timbers, to each alternate set, or to those portions only of the timbering of a level against which the timber's pressure is, or is likely to be, excessive. Of course, the full advantages of the system are obtained only when every set of timbers is braced.

Lower California Placers.

Late news from the Lower California Placer mines does not indicate any very promising prospects of a great mining field in that region. The lack of water is of course a very great drawback, even if the mines are as rich as was

Fig. 1.

Fig. 2.

FRENCH SYSTEM OF TIMBERING FOR MAIN LEVELS.

is rendered capable of resisting a very great pressure.

The operation of fixing these bracing pieces are performed in the following manner. The workmen first place the longitudinal in position beneath the caps, and fix it there temporarily with pieces of wire. The length of this piece may be from nine to twelve feet. The side longitudinals are placed and held in position in the same way. Two or three of the uprights are then placed at suitable points beneath the side longitudinals, and some of the struts are inserted obliquely and driven gently towards their ultimate positions. The whole of the bracing being thus rendered self-supporting, the wire is removed, and the remaining uprights and struts put in obliquely, and driven firmly into their positions with a heavy mallet.

If the correct length has been given to these several pieces, and the work is executed by an experienced man, a firm and unyielding framing

is first represented. Mr. P. B. Chison, who has just arrived at Guaymas from the gold fields reports as follows: Since the exodus of the Americans some considerable prospecting has been done, and all those who have worked at the placers are making something. One party now at Muleje has sixteen ounces, the result of three weeks' work. An expedition well prepared with provisions and all tools for mining, has left for the placers. Quite a number are coming in from the lower end of the peninsula. A new gulch has been discovered some five miles from the present placers and nearer to the Mission of San Gertrude.

In this connection we would call the attention of parties owning dry placer mines to a new machine (pneumatic sluices), recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, which is intended for this class of ground. The agents, J. H. Suggett, Carlin, Nevada, or J. M. Thompson, 1252 Market st., in this city, will put the machinery on any good ground for an interest in the same.

Booming.

The term "booming" is applied, in mining parlance, to an operation much resembling the old process of "flushing," as used in Yorkshire, for discovering lead lodes. A reservoir is first constructed at the head of the ground to be worked. Into this water is conducted, from the most convenient source still higher up, by flumes or ditches. These reservoirs vary in size from a small pond to an acre or two lake, and the ditches are often 8, 10 and 12 miles long. When the basin is full, and a continuous head of water is in running operation, gates are opened, letting loose the whole volume of the liquid, which tears down the mountain side in a huge volume, sweeping everything before it, carrying tons of boulders, gravel and dirt down to the gulch below. If auriferous ground is to be worked, a long and massive wooden flume is built at the foot of the hill, into which the debris is carried with all the force of the falling waters, and the sand and rocks washed along in its course, while the gold is deposited by its own gravity behind the riffles in the bottom of the race. These flumes are built with great strength and solidity to withstand the immense wear.

The self-acting gate, now considered the best (whereby the opening and shutting of the gate of the reservoir is made automatic), consists of a water-box suspended in guides, the rope from which passes over two pulleys, one of twelve feet and one of five feet, to the lower edge of the canvas gate (barred with strips of iron or two-inch timber). When the water in the reservoir reaches the proper height, a small flume conducts it to the box, which, when full of water, has weight enough to roll up the gate at the bottom of the reservoir from the bottom, allowing the water in the reservoir to issue through a gate (generally 4x6 feet in size). By the time the reservoir is nearly empty, the water in the weight box has discharged itself through holes, made for that purpose, in the bottom, and a weighted arm on the second pulley drops the gate to its place, when the pressure of the water keeps it in place, water tight. One man is considered ample force to run a boom, and his duties consist mostly in clearing timber from the ground to be worked and in breaking the larger boulders into sizes small enough to go through the flume, which is usually four feet wide, with a grade of one foot in twelve feet. The use of a boom permits the working of ground that could by no other means be made to pay. The experience of the Summit county, Colorado, miners goes to prove that, notwithstanding the large amount of water used and the velocity with which it rushes through the flume, the gold collects readily in the upper boxes of the flume, in which mercury is generally placed. Booming permits the working of claims that would otherwise be valueless.

MINING is being conducted with great energy in the San Francisco canyon, above Newhall, says the Los Angeles Times, the only drawback being the scarcity of water and the failure to make a dry washer a success. From the grass roots down there is a show of gold, and could water be put on the land fortunes might be made.

EXTENSIVE concentrating works is what is required on Wood River. All our ores will pay to concentrate. It will be vastly more economical to ship concentrations than to ship ore, even were the rate only \$15 a ton.

The Comstock Lode.

A Virginia *Enterprise* reporter has been interviewing Mr. J. C. Flood, the "Bonanza King," and from the published report we take the following:

"Have you faith still in the Comstock?"

"Yes, I think as I always did. When it comes to looking for a mine, the Comstock is about the only place where I would go to look for it just now. These other places, which we hear so much about, are all right, but the Comstock offers the best prospect. Of course, the thing to do is to find a mine, and while the outlook is encouraging, all conjectures are useless in regard to the future. Find a mine, and everything will come round all right. The Comstock, in my judgment, is the field for work."

"Very true, but if there is any foundation in the stories now being circulated, the Bonanza firm is losing control of the mines up our way."

"That's all nonsense. We have not lost control of any mine which we desired to hold. The Yellow Jacket, over which there has been so much talk, I did not want; because, under the present circumstances, we could do nothing with it. The group of which it is the center, is of no account, unless concentrated in the hands of one management. I advised Morrow myself to go in and secure the control of Yellow Jacket, while it was to be had for a song. Even if we decided to hold that mine, it could not be done without unnecessarily exciting the market. As soon as we make the slightest move, they all jump up. Morrow and his friends can pitch in, and no one is any the wiser."

"But what about Union and Sierra Nevada. They say that those mines have slipped out of your hands?"

"As I said before, that's all nonsense. We have no intention of giving up the north-end mines unless the stockholders are dissatisfied. We are getting down pretty deep there, but with economy and with the advantages we have now in the way of machinery and the knowledge acquired in regard to the best methods of exploring at that great depth, there is no reason to apprehend that we are making any mistakes. The ground is interesting, but that of itself is not sufficient. We must find a mine, and that's what the stockholders want."

"Then you don't entertain any apprehension in regard to water?"

"Not a bit. We can take care of all the water that may come our way. Until I saw Patton I had some misgiving on account of the great depth where we are working. He is a reliable, faithful man, and a more skillful engineer never worked on the lode. He never loses his head, and is always at work, planning and studying what is best to be done."

"Yes, that's what those who know the man in Virginia City says about him, but the incessant strain seems to be telling hard on him. Mr. Patton is beginning to look like another victim of overwork."

"You evidently don't know him. He is as fresh as a boy. Why, up at Mount Cory he was as young and as full of life and energy as ever. The way he went through those levels and took out samples from every corner surprised me. There are few men that have the physical or mental resources in them for work that Patton has to-day."

"Then you don't believe that deep mining is played out?"

"I do not. That's an old scare-crow. When we were getting into Consolidated Virginia we were told we were going too deep. I thought differently. You know the result, and there's no use my saying any more. The Sutor tunnel gave us a new surface—a new startling point."

"How deep, then, do you think you can go and still feel hopeful?"

"As deep as we can find the ore. Patton tells me that he can go down to the 4,000 level with his present facilities. But don't misunderstand me. We must find a mine. I can only say that the situation warrants looking for one, even at that depth. We are justified in considering the Sutor tunnel level as our starting point when we talk about depth. So we are really no deeper now than we were when I secured control of Consolidated Virginia. In other respects the situation is a much more difficult one. Our safety lies in the practice of the most rigid economy. The reduced market value of silver makes an important difference. The financial world has been educated to believe that the Comstock, when productive, turns out nothing but silver, and that fact keeps the price of silver down."

"You don't mean to say that the mono-metalists and bi-metalists are ignorant of the fact that for every fifty-five cents in silver we produce forty-five cents in gold?"

"I mean to say that it is almost a fixed belief that the Comstock is exclusively a silver producer. Deidesheimer's speech did the mischief. That speech, in which he exaggerated the product when we found the bonanza, was published in every financial center, and it left a deep impression. It will take them thirty years to find out that the Comstock yields gold, as well as silver. Silver went down soon after Deidesheimer's talk, and it has never come up since, and does not seem likely for a long time to recover from the shock."

"When shall we see you on the Comstock again, Mr. Flood?"

"I promised Mackay, before he went away, that I would visit Virginia City soon. I have a dispatch from him that he is now on his way back. He left Moscow a week ago, and is

coming right home. In a short while he will be back. Then he and I together will pay your town a visit."

"Well, it is encouraging, Mr. Flood, to learn that you think well of Virginia City. Our own people have never lost hope. But we felt depressed at times during the long gloom, and what with Mr. Mackay in Europe, Mr. Fair going abroad and the accounts of your buying real estate extensively in San Francisco, and building great warehouses, we had come to believe that the bonanza firm were turning the cold shoulder our way."

"A man ought to be allowed to buy a little real estate."

"But Mr. Fair gave us a parting kick. He told a New York reporter there was no improvement on the Comstock, and gave him to understand that while there was hope—that was about all we had left. That was not kind, when every miner on the Comstock knows that the prospect has not been so encouraging for five years."

"Mr. Fair should not have said what he did. If he has not been misrepresented in what he did say, he did wrong. The facts, Mr. Fair is not a well man. He is ill. Six months in Europe may cure him."

The reporter had informed Mr. Flood of his connection with the *Enterprise*, and before he left him asked him if he had any objection to his publishing the substance of the conversation which had taken place. Mr. Flood replied that he had no desire to be made conspicuous in print, but if it would do the people of Virginia City any good to know his views, they were welcome to them. He believed the Comstock was the best place in the world to-day to find a mine, and the problem, which requires skill, courage, perseverance and economy, was to find the mine. He had faith in the men who were trying to accomplish that result, and he had faith in the old lode as strong as in hy-gone days, when men could be found who spoke as disparagingly of it as some speak of it to-day. He said also that the contract which Sutor had made with the mines was a good thing for the tunnel and a good thing for the mining companies. That contract was made on his (Flood's) advice. But for it Sutor would have "gone broke." But the tunnel was to-day its own best vindication. Without it we would be helpless in the deeper levels. The situation was encouraging both above and below the tunnel level. We had all been in such a hurry to go down, down, that the upper levels had not been half prospected. Improvements were still under contemplation. He had been considering the practicability of introducing the electric light under ground, and was now awaiting the result of certain experiments to determine the best patent. The scheme would not only save candles, but, if successful, of which he had no doubt, it would conduce to the safety and comfort of the miners.

The Anti-Miners' Attack Upon the Drill Miners.

We have often warned our readers and the quartz and drift mine owners that the statements of the anti-debris lawyers and the officers of that association were not to be relied upon. They have repeatedly stated that they did not intend to attack any quartz mines or drift mines but only intended to close the hydraulic mines. We have often called attention to the legal conclusion that if they close one kind or class of mines they could close any and all mines, and urged upon mine owners, other than hydraulic, the absolute necessity of joining the Miners' Association or some other mode of defense to protect their property and interests.

In the early stage of the present litigation between the anti-miners and the miners, Judge Van Clief was perhaps the most prominent of the many legal advisers and counsel of the anti-miners. For some good cause he has for a long time past not appeared in any of the present suits, and had apparently remained quiet, removing his residence from San Francisco to Sierra county. The reason is now apparent, for a suit has recently been commenced in Sierra county by a person named Kennedy, who owns a small piece of land on Rock creek, against the Ruby Mining company, whose only property consists of a drift mine, forming a part of the well-known Bald mountain channel. This company, after expending a very large amount of money in running a long tunnel and prospecting, found the channel a few months ago. No sooner do they get fairly at work than the anti-miners turn up in a suit, brought ostensibly for Mr. Kennedy, in the Superior Court of Sierra county, by Mr. Van Clief, against the Ruby company, to enjoin them from muddying the water or using Rock creek as a place of deposit for the tailings from the drift mine. The complaint is similar, in almost every way, to the stereotyped complaints of the anti-miners in the suits against the hydraulic mines, and asks for the same relief, i. e., an injunction to prevent the mine from being worked.

If this is not a practical refutation of the assertions of the anti-miners, and a complete justification of our assertions, that the statements of the anti-mining lawyers cannot be relied upon in any way, then we are much mistaken. Our mine owners, both quartz and drift, who have hugged themselves with the promise of the anti-miners, may, and we trust will, now awake to the fact that it is war all along the line, and the quicker they enter the field and buckle on their armor for the fight, the better will be their chance of not being forced to sustain an

isolated defense. For, as certain as it is now that the Ruby drift mine has been attacked by the anti-miners, so will all the principal drift and quartz mines be attacked. It is only a question of time.—*Nevada Transcript*.

Carbonate, Colorado.

J. D. Taylor, a Denver real estate dealer, returned from a two weeks' trip to Garfield county. He spent several days at Carbonate, and brings back favorable reports from the new Colorado eldorado. A *Republican* reporter engaged Mr. Taylor in an interview, and in response to numerous inquiries gave the following information concerning that new mining excitement.

How to Get There.

The best route is by way of Red Cliff, which is reached by the Denver & Rio Grande railroad. From that place to Dotsero, forty-five miles distant, the journey is made with freighters, but Wall & Witter expect to have a stage line in operation in about a week. The route is down Eagle river. The journey is continued the next day to Dotsero, which is reached about ten o'clock.

Dotsero.

The town of Dotsero is located at the confluence of the Eagle and Grand rivers, and is surrounded by a fine agricultural region. Its altitude is about 6,000 feet, and the population numbers 300. It has been the winter rendezvous for carbonate pilgrims, and has about sixty tents and cabins. The bridge across the Grand at this point has a length of about 450 feet, and will be completed within about a week. Dotsero has three saloons and two hotels, but no doctors or lawyers have yet located there.

Dotsero to Carbonate.

It is about twenty miles from Dotsero to Carbonate. Leaving Dotsero, a journey of one and a half miles is made up the Grand to the mouth of Deep creek. Crossing Deep creek the old Indian trail is followed to Ute Park. In following this trail an elevation of about 4,000 feet is made in going a distance of five miles. The journey is then continued between Deep creek and Sweetwater, until the head of Deep creek is reached, about three miles from Carbonate. Up to this point but little snow is encountered, and Mr. Taylor expects this part of the route to be free from snow in about three weeks.

Carbonate.

Carbonate has an elevation of about 11,000 feet, and at the present time it has a population of about 300. Eight men remained there during the winter. About two months ago the population numbered fifty people.

The town is located in the mineral belt, and, according to the statement of Mr. Taylor, a part of the town site has been staked off into mining claims. The formation is limestone, and the mineral is found both in veins and deposits. The character of the ore is principally argentiferous, but that region also produces gray copper, zinc blend, iron pyrites and carbonates. The Ryan shaft, now being worked, is seventy-eight feet deep, and is located near the main street of the town. The tests of the ore from this property show eighty ounces in silver and twenty-two per cent lead.

Mining in Snow.

In some parts, the snow has disappeared, and yet mining is now being followed in other places by digging blindly through the snow. Mr. Taylor located a claim which was covered with three feet of snow. When the ground cannot be seen the miners drive stakes in the earth 300 feet apart, and after locating as much territory as one desires, they commence to sink blindly in search of mineral. Though Garfield county occupies the western territory of what was formerly part of Summit county, yet by special laws the claims have the usual size of 300 by 1,500 feet. This mining district is supposed to have an area of 10x25 miles.

Iron and Coal.

Mr. Taylor further reports that there are large quantities of coal and iron near Carbonate. About three miles south of the town there are large and almost inexhaustible quantities of coal, similar to that found at Canyon City. Hematite of iron is also said to abound in large quantities in the same vicinity. Owing to these great natural resources, Mr. Taylor predicts that the coal and iron industry will yet be a prominent business feature of this new district.

Other Resources.

Fine timber lands also abound in this district. Numerous small lakes are found, containing a bountiful supply of fish. The agricultural regions along the river are rich and fertile. The parks are filled with deer and antelope, and bears are quite numerous.

To Have a Railroad.

The Denver & Rio Grande railroad is making arrangements to build a railroad to Carbonate. The railroad has already been completed to Rock creek, and a surveying party is laying out a route to Carbonate. Nineteen miles of the route have already been surveyed. Mr. Taylor is well pleased with the country, and predicts for it a brilliant future.

The value of mining stocks upon the San Francisco lists a few years ago was \$275,000,000, says the *Bulletin*, but the whole list is not now worth more than \$5,000,000.

Copper in Arizona.

The Arizona *Silver Belt* says: The extent of the copper deposits of the country through which the A. M. B. road will pass is difficult to determine. In what is known locally as "the Verde country," they are far more extensive (area considered) than they are in Globe district, though the work done on them has been comparatively little. Considerable prospecting is being done, and claims are taken and held by men who trust to the A. M. B. railroad to make them valuable. So far as actual production goes, these mines have no record, due to the fact that they are far from the railroad, and have no wagon road over which to haul their supplies or millions. In Globe district, the area of country in which copper shows as a leading mineral is irregular but extensive. Two miles from McMillen, east, it shows in strong veins mixed with silver, and it also shows west of the Bloody Tanks, a distance, longitudinally with the copper belt, of thirty miles. It is about two miles across. From McMillen to Globe it does not crop much, but from the latter place to the Tanks it is always present. The principal development is included in an area embraced by a sweep of four miles from the east, around the north, to the west. The ore is found in veins of varying size. That of the Old Globe is 150 feet wide—the largest; and that of the Takoma has the greatest depth—450 feet. Both of these, and the Buffalo and Long Island are on true veins and yield a high grade of ore. Copper production may be said to have started with the Carrie company, two years ago; but they did not score a success because of faulty management, and the silicious character of their ores; the latter feature making it necessary to use large quantities of flux, thereby reducing the percentage of copper, to such an extent that (with the enormous freights charged) it could not be handled. The Buffalo company erected a smelter and ran it with much success, but they too had to succumb to the heavy outlays and the reduction in the price of copper. The Old Dominion company erected smelters where they had no mine, and spent money lavishly and foolishly until the advent of J. J. Williams who wedded the mines and smelters, and has made a continuous record such as never was known in the history of copper mining before. The Long Island company, under Frank Nicholson's management, produced a great deal of copper, but high freights have stopped the work. The Takoma, a rich property, and the Old Dominion must also stop until a railroad makes it possible to use lower grades of ore, and pay dividends to stockholders instead of enterprise-killing freights to the Southern Pacific railroad and teamsters. The copper product of this district, for the actual running days is a revelation, as it passes six tons per diem for each smelter. From the data furnished by the different superintendents, we gather that, 21,650 tons of ore have been treated; that 3,777 tons of coke have been used; that 3,159 tons of copper have been produced, and that \$211,716 have been paid for freight. There are six smelters in Globe, all of which must soon be idle; if there was a railroad, all of the companies but one would increase their plant, and new companies, now organized, would commence operations. It is safe enough to say that twelve smelters would be operating in this district, in six months after the completion of a railroad; and between Globe and the A. & P. road at least twenty. These would consume an aggregate of 160 tons of coke each day, or 58,400 a year, and produce—say 29,200 tons of copper. With the cognate interests that must necessarily grow up about such an enlargement of this industry, it would seem to be, and is, a cogent argument in favor of the building of the A. M. B. railroad, not only as an agent in developing the country's wealth but as a channel for profitable investment.

DEBBS SUIT.—A dispatch from Marysville, dated the 13th inst., says: The trial of the case of Allen S. Noyes vs. the Spring Valley Hydraulic Gold Company closed to-day in the Superior Court of Sutter county, before Judge Keyser. The case was taken under advisement. Judge Keyser will visit the mine and plaintiff's land. The plaintiff asks for an injunction to prevent the defendant from discharging water and debris through Dry creek into and upon plaintiff's land. The defendant's mine is at Cherokee, and valued at one million dollars. It is one of the largest and best equipped hydraulic mines in the State, using a constant daily supply of 2,200 inches of water. The tailings from the mine flow through Sawmill ravine into Dry creek, thence between many miles of embankment constructed by the defendant's predecessor. The old company still owns 42,000 acres of land on which embankments are built, the use of which defendant had acquired by lease. After leaving the canal the defense claim the water is settled in the lake on Koppel's land, and thence flows pure into Batte creek, from the headwaters of which 1,800 of the 2,300 inches used at the mine is taken. The plaintiff, however, claims that water and slickens flow from the mouth of the canal down upon plaintiff's land four miles below. This trial lasted eight days and a great deal of contradictory testimony was introduced. The suit is not fathered by the Anti-Debris Association, and it is presumed that if an injunction be granted the plaintiff will sell his land to the defendant, and the latter's operations will be resumed.

MECHANICAL PROGRESS.

Hardening and Tempering Steel.

Prof. Chandler Roberts, of London, England, in a recent lecture on theoretical considerations connected with hardening and tempering steel, stated it to have been long known that there are extraordinary differences between the properties of wrought iron, steel and cast iron, but our knowledge that these differences depend upon the presence or absence of carbon was only a century old.

It was not until 1781 that Bergman, Professor in the University of Upsala, showed that wrought iron, steel and cast iron leave, when dissolved in certain acids, amounts of a graphitic residue, varying from one-tenth to two and a half per cent, which are essential to the constitution of these three varieties of metal. Bergman's work led many early experimenters notably Clouet, in 1796—to attempt to establish the importance of the part played by carbon, and Clouet converted pure iron into steel by contact, at a high temperature, with the diamond. Prof. Roberts said that this experiment had been repeated by many other observers with varying success, as in all the earlier work the action of furnace gases which had not been excluded, might have converted the iron into steel without the intervention of the diamond.

It remained for Mr. W. H. Pepsy to repeat Clouet's fundamental experiments under conditions which rendered the results unequivocal, by employing electricity as a source of heat. This experiment, which had been communicated to the Royal Society in 1815, was then performed in the way Pepsy had indicated.

It was then shown that in soft, tempered and hardened steel respectively, the carbon has a distinct "mode of existence," as is indicated by the widely different action of solvents on the metal in these three states. The evidence as to whether carbon in steel is combined in the chemical sense, or is merely dissolved, was then considered at some length, special reference being made to the results obtained by various experimenters, from Berzelius and Karsten to Professor Abel, of Woolwich.

Professor Roberts stated that the researches of Troost and Hanteculle afforded strong evidence that in "white" cast iron and steel the carbon is merely dissolved, a view which he adopted, as he did not consider it to be at all in opposition to the fact recently shown by Professor Abel, who had shown that in the carbon left by the slow action of solvents on soft steel is a carbide of iron. The various physical, as distinguished from the chemical, theories that had been propounded from the time of Reaumur (1722) to that of Akerman (1879), to account for the "intimacy of the relation" of carbon to iron in hardened, as compared with soft, steel were then described.

In recent years much importance had been attached to the physical evidence as to the peculiar constitution of steel, and it had been shown that there is a remarkable relation between the amount of carbon contained by different varieties of steel and their electrical resistance. Some of the very interesting experiments of Professor Hughes on this point were then exhibited and described. Professor Roberts concluded by saying that the value of the early work by Bergman and Reaumur had rather been lost sight of in recent discussions; and the importance of the degree of carburization of steel, from the point of view of its technical application, was illustrated by reference to a series of curves. It was incidentally mentioned that in the case of the variety of steel used for the manufacture of coinage dies, the presence of one-tenth per cent of carbon more or less than a standard quantity, made all the difference in the quality of the metal.

Modern Guns and Projectiles.

The United States Board of Engineers for Fortifications has recently submitted a valuable report upon the practice in Europe with the heavy Armstrong, Woolwich and Krupp rifled guns. The conclusions of this report are as follows:

"Experimental firings for penetration during the past twenty years have determined:
"1st. That wrought iron and cast iron, unless chilled, are unsuitable for projectiles to be used against iron armor; that the best material for that purpose is hammered steel or Whitworth's compressed steel.

"2d. That cast iron and cast steel armor plates will break up under the impact of the heaviest projectiles now in service unless made so thick as to exclude their use in ship protection.

"3d. That wrought iron plates have been so perfected that they do not break up, but are penetrated by displacement or crowding aside of the material in the path of the shot, the rate of penetration bearing an approximately determined ratio to the striking energy of the projectile, measured per inch of shot's circumference.
"That such plates can, therefore, be used in ship construction, their thickness being determined by the limit of flotation and the protection needed.

"4th. That though experiments with wrought iron plates faced with steel have not been sufficiently extended to determine the best combination of these two materials, we may nevertheless assume that they give a resistance about

one-fourth greater than those of homogeneous iron.

"5th. That hammered steel in the late Spezia trials proved superior to any other material hitherto tested for armor plates. The nineteen inch plate resisted penetration and was only partially broken up by four shots, three of which had a striking energy of between 33,000 and 34,000 foot tons each. Not one shot penetrated the plate. Those of chilled iron were broken up, and the steel projectile, though of excellent quality, was set up to about two-thirds of its length. This experiment seems to promise the solution of the problem to determine a material for armor plates which, though limited in thickness to the carrying capacity of the ship to be protected, will still have sufficient resistance to break up the projectiles of the largest guns now in the naval service, without being penetrated or broken by the projectile.

"It seems probable that a hammered steel plate, like that tried at Spezia, if equal in thickness to the belt armor of the Indefatigable (22 inches), would stop the shot of the 100 ton gun (Armstrong) fired with its greatest practicable velocity.

"Finally, these later experiments confirm this Board in its opinion, enunciated some years since, that, while the 12 inch rifled gun may prove a sufficient armament for the barbettes batteries of our sea coast defenses, as against the lighter ironclads of foreign navies, iron turrets, armed with guns of 100 tons weight at least, will be needed to meet the attack of armored ships of the latest construction."

The 100 ton chambered Armstrong gun, throwing a projectile of a ton weight, and fired with a charge of over 700 pounds of powder, may be taken as a sample of the monstrous requirements of modern war. Such guns must be both made and operated by machinery.

FAST WORK IN A CARRIAGE SHOP.—At the annual dinner of the Carriage Builders' National Association, in Philadelphia, Hon. Phineas Jones told of fast work he had lately witnessed in a carriage factory that turns out from 15,000 to 20,000 carriages a year. He said: "I saw them setting tires. I noticed how fast they put the tires on the wheels. They put on fifty-three sets of tires in fifty minutes. This is work, and a fact. One man put the tires into the oven and took them out after they were heated. There were about sixteen tires heated all the time in the oven, and then there were two rollers driven by a belt revolving all the time, with a strong fire at the rear of it, and when the tires were taken out two other men stood there and put them on. I timed them, and they put on a set a minute. And the man told me that one day, when the tire setter wanted to be away the next day, and it was then five o'clock in the afternoon—he told him those wheels had got to be tired the next day, and he said: 'I will tire them to-night.' There were fifty-three sets of them, and he put them on in fifty minutes. Those are facts. I noticed one man setting tires, and I timed him with my watch. He lit the forge and put on a tire a minute. I said that is lively work."

NEW ADAPTATION OF ELECTRICITY.—One of the most ingenious adaptations of electricity, recently introduced, is that by which machinery, when in motion, may be instantly stopped, as in the case of an engine. A wire rope, coiled around the stem of the throttle valve of the engine, carries a weight which is held in place by a rest, and the whole arrangement is such that the passing of an electric current along a wire releases this rest and causes the weight to fall. The tension thus thrown upon the wire rope acts upon the throttle valve, cuts off the supply of steam, and, consequently, stops the machinery. Buttons, with wire connections, are placed in different parts of the works, and on pressing any one of these the passage of an electric current acts as above mentioned. In any factory these electric buttons can be placed in every room, or several of them in a large room, as may be required. Should any one happen to be caught by the machinery, the simple pressing of a button in the most distant part of the factory will quickly stop the whole.

DRILLING GLASS.—For drilling holes in glass, a common steel drill, well made and well tempered, is the best tool. The steel should be forged at a low temperature, so as to be sure not to burn it, and then tempered as hard as possible in a bath of salt water that has been well boiled. Such a drill will go through glass very rapidly if kept well moistened with turpentine in which some camphor has been dissolved. Diluted sulphuric acid is equally good, if not better. It is stated that at Berlin glass castings for pump-barrels, etc., are drilled, planed and bored, like iron ones, and in the same lathes and machines, by the aid of sulphuric acid. A little practice with these different plans will enable the operator to cut and work glass as easily as brass or iron.

FIRE BRICKS FROM FLINT.—A new manufacture has sprung up in England, and one which, according to the *Iron* promises well for those who have embarked in it. This is the manufacture of fire bricks from flint, at works which have lately been started at Charlton, Kent, by the Thames Flint Fire Brick Company. The bricks are manufactured under Sir Henry Edwards' patent. These bricks have been tried in various steel and iron works furnaces developing intense heat, including Siemens' regenerative furnaces, and the results in all cases are reported to be most satisfactory.

SCIENTIFIC PROGRESS.

Tornadoes.

Sergt. John P. Finley, Signal Service officer at Kansas City, Mo., has published, in a pamphlet on tornadoes, some useful directions concerning the course to be taken to escape the attending danger. The inhabitant of a tornado-frequented district must be watchful in the season of visitations, for he can never know when the destruction will come upon him. On the first sign of the approaching vortex he must run—always to the north, unless by going in that direction he will have to cross the entire path of the storm. If he is nearer to the southern edge than to the center of the probable path, he may go south, bearing slightly east, but in no event run directly to the east or northeast. It is impossible to save any building which may lie in the path of the tornado, or any property that cannot be got out of its way. No material, no method of construction, can be competent to resist the raging destruction. Nothing rising above the ground can escape it.

The most practicable measure of precaution is to construct a "dug-out" at some suitable point, within easy distance from the house, to serve as a place of refuge or shelter. The retreat should be entirely underground, with a roof at least three feet thick, not rising above the surface of the earth, and entered from the northern or eastern side. A "cellar cave" may be constructed from the cellar, if the house has one, to serve as a substitute for the "dug-out." It should be excavated from the west wall of the cellar, toward the west, and should be made as complete and secure as the "dug-out." If, however, the storm cannot be escaped, if no refuge is at hand, or there is not time to get to it, the safest thing to do is to place one's self against the west wall of the cellar, face toward or against the south wall, as near the southwest corner as possible. The northeast quarter is in any case a fatal position, and should always be avoided. If one is actually overtaken by the tornado, his only resource is to cast himself face downward upon the ground, with his head to the east and his arms thrown over his head to protect it. If a stump or large stone, or anything heavy, that the wind will not blow over, is near, he may get a trifle of protection by throwing himself to the eastward of it. If in a house with no cellar, he should get into the west room, on the ground floor, if possible, and away from all stoves and heavy furniture.

The people of towns might find it to their advantage to provide for having a watch, to be on duty on all days when the air bears the premonitory symptoms of a violent wind-storm, to give a signal to the whole population on the appearance of the first real threatening signs. The signs of the formation and approach of a tornado cloud are distinct and sufficiently suggestive to afford opportunity for timely and concerted action. Sergeant Finley, is continuing, his investigations of the phenomena of tornadoes, and he has prepared three full schedules of minute inquiries calling for the facts attendant upon the appearance of the storms, which he sends to persons who were within the path of one, who were on the outer edge of the path, and who were within 10 to 100 miles from it.

SHALL WE SMELL BY TELEPHONE?—Who shall say that the principle of the telephone may not be applied to other senses than that of hearing and sight? "A few years ago," said a distinguished electrician, recently, "the distance at which you could hear a sound was limited. Now it is practically without limit. You can smell a flower only at a short distance. I do not see why a telephone for the nose might not enable you to smell a rose in New York, even though you were located in Atlanta. So of the taste and touch. A new application of the principle of the telephone might enable you to remain in Atlanta and kiss your wife in London, or taste a berry in Paris. The telephone has already made a clumsy step in this direction for the sight. We would have thought the man crazy a decade ago who said you could stand in New York in 1883 and hear every note of a concert in Boston. Quite as crazy as the man who now predicts that in 1903 you may sit down in Atlanta, see a theatrical representation in Cincinnati, smell a bouquet in New Orleans, taste a fresh oyster in Baltimore, and shake hands with a friend in Savannah, all at the same time. In these days it is only the impossible that happens."

WHAT CAUSES THE TIMBER LINE.—The cause of what is known as the timber line on high mountains continues to be discussed in scientific periodicals, and the attempt continued to connect the line in some degree with mean annual temperatures. The writer of this paragraph has had the matter in mind when on these high elevations, and the explanation seemed very simple. On all these high peaks there is a continuous, though in some cases slow, descent of the soil from the summit to the base of the hill. He has never seen a case, where there was soil enough to grow a tree, that trees were not growing. As the wash from rain or melting snow will be nearly uniform in a given range, there will be of necessity some uniformity in the timber line. On Mount Washington and other high places, little plots of dark vegetable earth can often be found far above the present timber line, the remains of trees which existed before the earth was washed away. What is called the timber line seldom shows graduated

sizes as a mere matter of temperature would call for. Generally the line is formed of very small trees, and immediately scrubby plants, from the absence of deep soil, begin. *N. Y. Independent.*

TWINKLING DURING AURORAS.—Arago, in his admirable note on Scintillation, says that at the end of the eighteenth century Dr. Usher remarked, that at Dublin the Northern Lights made the stars singularly undulating in telescopes, and that according to Neckers, de Saussure, and Forbes, the stars do not twinkle in Scotland unless there is an aurora visible. Montigny's observations of scintillations have coincided with many visible auroras. At each one of those coincidences the intensity of the scintillation was much greater at the moment of the aurora than on the previous evening or on the following day, when the atmospheric conditions were the same but no aurora was seen. When a magnetic perturbation is noticed at the Brussels observatory without any accompanying visible aurora; the intensity of the scintillation suddenly increases, and it is then much greater than on the previous evening or on the following day under the same atmospheric conditions, with the exception of the magnetic perturbations. *Comptes Rendus.*

CONDUCTIVITY OF CARBON.—A contribution to the theory of the carbon telephone transmitter is to be found in recent researches by Messrs. J. Probert and A. W. Soward. It has long been known that carbon has the power of absorbing and condensing gas within its pores, and also that resistance of carbon powder to an electric current through its mass is not a true resistance, but may be resolved into two factors—namely, the true resistance of the carbon particles and the resistance of or disturbance occasioned by the gas or air confined within the existing spaces. In blocks of solid carbon the air spaces are naturally smaller, and the resisting or disturbing influence is weaker than in the case of carbon powder, but still it exists, and the experiments of the gentlemen above mentioned prove that the conductivity of porous carbon in different gasses at different pressures varies with the chemical nature and density of the absorbed gasses.

THE RECENT ECLIPSE OBSERVERS.—The American eclipse expedition, which went out to the Caroline Islands, in the Southern Pacific, last March, to observe the total eclipse of the sun, has arrived in this city, on their way back. The observations made were very valuable and highly satisfactory. The chief work consisted, first, in the strong evidence obtained of the non-existence of a planet interior to Mercury. This result, in a scientific point of view, is very valuable. Most of the work done is of such a nature as not to admit of a popular statement, but it is regarded as entirely satisfactory to the astronomers. The English party photographed the spectrum, but their results cannot be stated until after the photographs have been examined in London.

MOTION OF SUN SPOTS.—Spencer, in a letter to Faye, reports the results of comparisons of his observations for twenty years, which seem to indicate a slight tendency in sun spots to move towards the equator, between the parallels of 5° and 10°, and a slight tendency to move towards the poles between the parallels of 20° and 25°. Carrington and de Rico found that the direction towards the equator predominated up to 15° of latitude, and towards the poles in higher latitudes. The tendencies were so slight that Carrington did not attach any importance to them. Faye regards these results as fatal to the hypothesis of Siemens, for if the sun is fed by an influx at the poles, he thinks that there should be a uniform tendency of the spots towards the equator in all latitudes. *Comptes Rendus.*

MOVEMENTS OF SUBMERGED BODIES.—In defending his hypothesis against the attacks of French academicians, Dr. Siemens refers to the experiments of Froude, at Torquay, under the direction of the English Admiralty. He arrived at the unexpected result, that a submerged body, if it moves with a uniform velocity through a perfect fluid, will encounter no resistance whatever. By a "perfect fluid" he understood a fluid free from viscosity or quasi-solidity, and in which no friction is caused by the gliding of its particles over one another or over the surface of the body. The luminiferous ether is presumably such a fluid, and the discussion of Siemens' theory cannot be settled until all the consequences of perfect fluidity are duly settled. *Comptes Rendus.*

PRESSURE BATTERY.—A. P. Zazareff has addressed a note to the French Academy relative to an electro pressure battery. The production of electricity is due to the passage of a solution of glycerine, under the action of a pressure which is more or less severe, through a mixture of coal and anthracite. *Comptes Rendus.*

MORE FOSSIL DISCOVERIES AT CARSON.—Another important discovery was made 14th inst., in the State prison quarry, at Carson. A few yards from the alleged prehistoric tracks, ten well-preserved teeth were found, about five inches long, recognized as having belonged to the species known as the saber-footed tiger.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior in proximity to the mines mentioned

CALIFORNIA.

Downs.—*Amador Ledger*, June 16: The Downs mine made a clean-up last week for a month's run, amounting to about \$4000. The mill has closed down, as the water supply will not be sufficient to insure another month's run. There is plenty of rock in sight, enough it is said to last for a couple of years. Sinking, however, is to be prosecuted during the period of forced idleness at the mill. The shaft is to be carried 100 ft deeper, which will give a total depth of 600 ft.

ous.—The first clean-up of Morgan's mill was made a few days back, based on good authority that the yield of the mill, better in fact than was anticipated, was not in a position to give the expectation that the yield was over \$2,000.

act figures, except that the yield was over \$3,000, which would give from \$6 to \$7 per ton. The hydro-
draulic claim, at the Oneida flat, which has been idle
for sometime for want of lumber, started up again
the other day. A splendid strike is reported, at a
spot half a mile or so north of Plymouth, on the
road leading to Nashville. Parties who have seen
specimens of the quartz say it is studded with gold,
and the discovery bids fair to create something of an
excitement. As usual, several claimants have already
appeared to the property, and vexatious litigation is
likely to be the result. The Loyal Lead mine is be-
ing worked with very encouraging prospects. The
first clean-up panned out \$2,000, which, it is said,
was more than sufficient to pay expenses. The
present crushing is expected to surrender at least
from one-fourth to one-fifth more than the last.

Calaveras.

GOOD DIRT.—Calaveras *Chronicle*, June 16: We have been informed that the gravel in the Empire mine in Old Woman's gulch, averages over \$1.50 to the car-load, and that there is plenty of it. That sounds like business. In the near future we shall endeavor to give a full description of this valuable property.

ANNALS.—Work

THE FAHEY TUNNEL.—Work is progressing favorably in the tunnel claim owned by Fahey & Co., near the French hospital. Tunnel No. 1 is in 200 ft., at the end of which a "raise" of 12 ft. was made and tunnel No. 2 run, which has now reached a length of over 200 ft. For a considerable distance the tunnel was run in old works which were badly caved and required a great deal of timbering. The object for which the tunnels are being run is to reach the channel in the Stockton Hill ridge.

200 Yellow Jacket

Mining stocks have fluctuated considerably this week, but have been more downward than the other way. Yet at the principal mines, on the Comstock and at Bodie, nothing has occurred to change prices five cents either way.

At the north end, nothing more is known of the ore vein on the 3000 level than when the joint Union and Sierra Nevada winze was first started. All work is still to the east of where the ore body cut on the 2900 will strike the 3000 level. Nothing more is known of this deposit of ore than was seen where it was mined on the 2900 level. The diamond drill will not be used in the crosscut, unless indications of a dangerous flow of water are seen. At the Yellow Jacket they are extracting about 150 tons of ore per day, and are opening new ground, which will probably considerably increase the daily yield. Much good ore is still being found in the Belcher and Crown Point mines.

Pinal Con., June 4th to 8th, inclusive, \$9,110; Contention, 9th, \$23,980; Bodie Tunnel, 13th, \$3,195; Diablo, 11th, \$8,297; Syndicate, 5th, \$9,042; Stan-
lard, 11th, \$21,369; Mt. Diablo, 14th, \$6,336; Northern Belle, 14th, \$7,381; Pinal Con., 9th, \$1,124; Bodie, 18th, \$6,660; Head Center and Tran-
quillity, 16th, \$4,973; Contention, 16th, \$22,333; Pinal Con., 10th to 15th, inclusive, \$5,625; Han-
auer, 13th, \$2,320; Horn Silver, 13th, \$9,000; Storm-
out, 14th, \$3,240; Nevada, 14th, \$1,870; Horn Silver,
14th, \$9,000; Hanauer, 15th, \$2,230; Horn Silver,
15th, \$9,000; Alice, 15th, \$22,984; Horn Silver, 16th,
\$9,000; Tintie, 16th, \$3,650; Turrill, 16th, \$1,489;
Hanauer, 17th, \$4,300; Horn Silver, 17th, \$9,000.

AN oil well is being sunk on the summit of the range of mountains back of the Ojai, Ventura.

WE would advise all parties looking for work to stay away from Grantsville. There is nothing being done in any of the mines, and we are under the impression that things will remain as they are until his Satanic Majesty influences the powers that control the production of the precious metals to order it otherwise.—*Grantsville Bonanza*.

CONSIDERABLE excitement prevails in Bodie over recent mining discoveries about the head of Parker canyon, and also over developments in other portions of Prescott district.

THE trial of the debris suit of Noyes vs. Spring Valley Hydraulic Company has been commenced in Sutter county.

A FINE vein of building rock has just been discovered on the Los Felis rancho, Los Angeles county.

last Tuesday. He received per railroad a large number of ore sacks and has gone at work on the Drummer Boy mine, in Mazourka canyon, to ship ore already out and to extract more— as many carloads as can be found that will pay.

RICH GRAVEL.—Homer *Index*, June 16: The Virginia Creek Hydraulic Mining Co. is reported to have cut into some exceedingly rich gravel—\$2.50 to the pan. The Gorilla tramway will be completed in a few days, when the hauling of ore will be commenced and the reduction works started up. William Erwin and Charles L. Drew have leased the Mocking Bird mine, and are now extracting ore to be reduced in the Parsons astrata.

OLD MACK MINE.—*Transcript*, June 17: Work will be resumed to-morrow in the Old Mack mine at Canada Hill, after a brief suspension on account of the Eastern owners not being prompt enough in making a needed remittance. The incline, which is down 125 ft, will be sunk deeper. The 6 and 4-inch pumps in use are not powerful enough to handle the water, and a 10-inch pump will be substituted for the 4-inch one.

RICH ROCK FROM THE SLATE RANGE.—*Grass Valley Union*, June 10: A clean-up of 17 loads of quartz from the Slate Range (Perrin's) mine, was made at Sothern's mill on Wednesday, which yielded \$146 to the load. A previous crushing went some thing like \$82 per load. This rock is a portion of a tribute contract of 50 loads which is being taken out by working miners. They have the ground opened with enough rock in sight to complete the contract which is expected to yield equally as well as that which has been taken out. In the meanwhile the proprietors are sinking a whim shaft on the ledge at the same point on the vein, and will be able to work down on the incline over 300 ft without having to pump, as the vein is drained at that depth by a tunnel.

CRESCENT MINE.—Greenville *Bulletin*, June 16. During the absence of Mr. Davis at Virginia City the mill and all work in the mine was stopped. Immediately on his return last week he resumed work in both mine and mill, and now everything is going on as usual. There is some difficulty or misunderstanding between Mr. Davis and parties in San Francisco who are interested in the mine. A clerk sent here by them, and claiming to be acting under orders from them, ordered the mine and mill stopped as stated. Mr. Davis regards this man as his subordinate, and will not permit a mere clerk to interfere with him in the management of the mine. Mr. Davis claims a title in the property and a personal interest in the working of it, and seems to hold that if the others do not choose to be interested in the work there is nothing to prevent him from continuing it on his own account.

GREEN MOUNTAIN MINE.—The old mill was stopped on Sunday to admit of some repairs in the machinery. This will be finished about Friday, when the mill will again be started up. The new mill is running steadily as usual. Some very good ore has lately been taken out in the upper levels, the yield of bullion showing a gratifying increase. In the tunnel the ledge has improved very much in appearance during the past few days. The walls have become better defined and the quartz is now of such a character as warrants the belief that the expected pay ore will be cut into very soon. In fact it is quite reasonable to believe that a good chimney may be found any day, or even any hour.

RICH.—*Mt. Messenger*, June 16: The lucky owners of the Four Hills Quartz Mine, near Eureka, Plumas county, have a bonanza in the shape of a pocket, nearly all gold. Pieces, weighing several ounces, of the pure metal, are taken out; and the ore is said to be rich beyond any other seen in that valuable mineral region.

San Bernardino.
ALHAMBRA. -Calico Print, June 16: The large force of men that have been employed on this mine has been withdrawn, and only three men are working at present prospecting an open cut. The bin is full of first-class ore.

LYON.---Since the connection of the two tunnels, making a continuous tunnel through the hill, stoping has been going on energetically, and a good quantity of ore that will average well has been taken out. The ledge is four or five ft in width, and the paying streak about two ft. This mine has an exceedingly fine prospect. It is the intention of the owners to commence hauling ore to the Pioneer mill at Hawley's in a short time.

DUNDERBERG.—The shaft in this mine is down 30 ft on the extension of the body of ore that runs through the Gobbler and is equally as rich. The cars are kept busy running the ore over the tramway, a distance of 550 ft, into the ore bin.

GOHBLER. This promising mine, one of the excellent group belonging to the Alhambra M. & M. Co., is still progressing in its developments; 18 men are taking out a large quantity of good ore, there being 50 tons of the same in the bin. Two teams are kept busy daily hauling ore to the mill. Sinking in the shaft continues and stoping has been commenced in both tunnels. An ore body ten ft in width has been opened on both sides of the shaft, which extends the entire length of the tunnels and has every indication of going down to an indefinite distance. The yield in bullion from this mine is at present considerable, and as work is now performed underground, the miners will not be so affected by the heat as to be obliged to suspend work during the heated term.

COMET. This mine, so promising and so favorably located next to the Little V is owned by Tom McFarlane, J. W. Waters, Jr., and Jack Cokeran. It has been thoroughly prospected with most favorable results, ore being uncovered in several cuts. A good road has been recently graded to the mine, which reduces the expense of getting the ore to the mill. In a few days teams will commence hauling the ore to Hawley's station.

SNOW BIRD.—Work is progressing on this mine slowly but surely. The results of developments lately have been quite encouraging. In the north-west corner of the claim two men are taking out ore in small quantities, yet it is exceedingly rich.

PUMPING.—*Mt. Messenger*, June 16: The B. M. Ex. Co. have started up their pumps at the Pliocene

shaft, water in the South Fork having slackened off to such an extent that they were not able to wash all the gravel they are getting out. The American Hill Co. expect to finish cleaning up on Saturday. They have had another cave since last week, covering up more of their bottom. The yield this season will be no fair criterion of the richness of the mine.

UNCAS.—The Uncas Co. did not redeem the Hog canyon property at the expiration of the time of redemption it having expired a few days since. P. A. Lamping and Capt. Mead, of Oakland, are now up looking at the property. Mr. Lamping expects to take charge of and to develop the property at no distant day. The face of the North America tunnel, run from near Gilsonville, Sierra Co., is now in Plumas. The gravel pays \$2.25 per carload. There are no idle men in Downsville. All the miners here, as elsewhere throughout the county are busy in their claims. Sierra's gold yield this year will be larger than for many years past. Work on the foundation of the Sierra Butte quartz mill, has been commenced at Sierra City. The Bald Mt. Co., at Forest City, last week, cleaned up 180 ounces of gold.

YIELD.—The yield of the Ex. Co. last week was 110 ounces, working 20 breasters. Several coarse pieces were found.

Trinity

PROSPECTING.—Trinity Journal, June 14: Prospecting in Bullychoop district is being vigorously prosecuted and rumors of new finds reach us every few days, without sufficient particulars, however, of which to make an item. Send us the facts if you have anything worth mentioning.

NEVADA.

Washos District.

CIDELLAR.—Virginia Enterprise, June 16: The last work done in this mine was a drift started June 4, at a point 12 ft west of the main lateral drift in crosscut No. 3. This was pushed ahead 22 ft in quartz, clay and porphyry, when work was suspended and the main south drift temporarily bulkheaded to keep back the heat, when the force of miners was transferred to the Hale and Norcross to assist in making an air connection between the 2400 and 2600 levels. The men are still at work in an upraise on the 2600 level of the Hale and Norcross.

UNION CON.—At the 3000 level a station has been cut out and a west crosscut started.

SIERRA NEVADA.—On the 3000 level a station (joint with the Union Con.) has been completed and a west crosscut started.

HALE AND NORCROSS.—The winze below the 2600 level is down about 27 feet. The ore on the west side still continues. The upraise from the 2600 to meet the winze coming down from the 2400 level is up 10 feet. On the 2400 level the winze has been hauled out nearly down to the 2500 station.

SAYAGE.—No work is being done at present in this mine, but once connection has been made between the 2400 and 2600 levels and a good circulation of air obtained, prospecting operations will be resumed under more favorable circumstances than at any time during the past seven or eight years.

YELLOW JACKET.—Are extracting some 150 tons of ore daily, and are doing a good deal of prospecting; also are cleaning out and retrimming old drifts at points where ore is likely to be found. They are now taking out nearly \$80,000 per month.

OPHIR.—Good progress is making in the work of repairing the old Central tunnel, and in the preparation for hoisting ore at the old croppings.

GOULD AND CURRY.—West crosscut No. 2 on the 2500 level is now out over 500 ft. The material is quartz, clay and porphyry. The porphyry is quite hard.

MEXICAN.—On the 2900 level the upraise to meet the winze down from the 2700 level is progressing at the rate of from 10 to 12 ft per week.

CON. VIRGINIA.—Sinking on the C. & C. winze progresses at the rate of 10 to 12 ft per week. On the 2700 level the southeast drift is being repaired and a drain is being cut.

SCORPION.—On the 500 level the west drift is being advanced at the rate of 12 ft per week. The ground is the usual vein material of that section.

ANDES.—Some very fair ore is being found, and the indications are favorable at several points, where promising streaks of quartz are coming in.

Belmont District.

PROGRESSING.—Belmont Courier, June 16: The work of repairing the Belmont mill is progressing steadily.

Columbus District.

NORTHERN BELLE.—The southwest drift on the fifth shaft level has been extended 8 ft during the week, its total length being 114 ft. The formation is hard quartz, carrying streaks of sulphurets which give assays as high as \$40 per ton. The crosscut to the south, on the same level, has been advanced 10 ft into ground promising well for ore. Some ore of a very good grade is being extracted from the seventh and ninth levels. Ore hauling was resumed on Tuesday last, and was the first delivery for a week. The force at work in the extraction of ore has been kept up meanwhile, the surplus being stored in the chutes in the mine. Owing to the stoppage of the mill but one shipment of bullion has been made. This was on the 14th instant, and amounted to \$7,381.08.

MOUNT DIABLO.—The stoppe from winze No. 2 shows several seams of \$70 ore, in all about 2½ ft in width. A stoppe has been started from the east drift, on the second level, and has cut 15 inches of \$75 ore. The stoppe above the west drift from the Callison winze is looking well and yielding a number of tons of \$80 ore daily. The ledge averages fully 2½ ft in width, and in the center of the stoppe there are fully 5 ft of \$100 ore.

Jefferson District.

ORE.—Belmont Courier, June 16: Charles Kanrohat has struck a good body of paying ore in one of his mines at Jefferson.

The Jefferson S. M. Co. is prosecuting the work of development with energy. The mill is running nicely, producing the usual quantity of fine bullion.

Pluto District.

MINING NOTES.—One-half ton of ore per day is being sent to the surface from the Fair Play on Alhambra hill. In the Western Globe a drift from the 120 level is being run on good ore, and a shipment will soon be ready for the furnaces. Richard Berry-

man & Co. are taking some good ore from the Uncle Sam tunnel. The Jones Brothers have been shipping some very good ore from the Queen mine to the Richmond furnaces. The Queen mine is situated on the west side of Silverado mountain, adjoining the old Resene, and has been an ore producer from the grass roots. The Silverado M. Co. are driving their tunnel ahead to connect with an ore body that has been traced from the surface to a depth of several feet and a large quantity of ore taken from it. M. B. Bartlett & Co. are actively at work upon the old Champion mine on Alhambra hill. O. H. Smith and Richard Berryman Jr. have run a tunnel along the contact of the limestone and trachyte.

Reveille District.

AT WORK.—Belmont Courier, June 16: Mine owners are hard at work in Reveille district, this county.

Safford District.

THE ONONDAGA.—Safford Express, June 16: The shaft near the crest of the hill is down 15 ft, the ledge showing strong in the bottom. Foreman House will erect a windlass as soon as timbers can be got across the Humboldt. The lower tunnel is being driven in as fast as practicable by two shifts. No ore is being broken for want of room to place it, every available part of the dump space being filled to overflowing. The Humboldt is still rising, and unless it recedes soon work is likely to be suspended.

OUR ORES.—It seems somewhat strange that Safford ores can be shipped to Salt Lake City and worked at less rate than in our sister town Eureka, though such appears to be the fact. It seems to us that satisfactory terms could be made with the E. & P. road and the smelters at Eureka by which our ores could be shipped to that place and worked at a profit. At least a fair test can be made, and we are informed that Supt. Read of the Eureka Con. is willing to make such test and if possible ascertain if our smelters can compete with those of Salt Lake. The E. & P. road, we feel confident, will offer liberal inducements, and in so far as the experience has never been tried, we suggest that some of our mine owners ship a car-load of ore to Eureka, as it will prove the means of settling all further doubts in the matter.

San Antonio District.

LEACHING.—Belmont Courier, June 16: George Nicholl & Co's leaching works are still running successfully in San Antonio district, this county.

Santa Fe District.

BRADLEY'S LAST FIND.—True Fissure, June 16: Santa Fe district is full of life at this time, some good prospects being found and all the mines at full tide of industrious development. The Rattlesnake is a promising claim owned by Owen Bradley. It is opened to a depth of 30 ft, where it shows a ledge of 8 ft. The average assays have been very encouraging, going as high as \$80 in gold with a fair showing of silver. Mr. Bradley has several tons of ore on the dump, from which he expects to make a shipment very soon.

Taylor District.

ITEMS.—White Pine News, June 16: Joe Carothers has put about 20 men to work on his company's mines. The Monitor is employing 32 men. This is a \$4 a day camp, and woe to the man who would offer to work for less. Joe Carothers commences this week to grade for his new mill. There are lots of men here, ready to do the work at short notice. The Monitor mine is looking well, with plenty of good ore in sight. W. G. Lyons, who owns a third interest in the property, looks after the mine. Robert Briggs will superintend the mill during McGill's absence East.

Tuscarora District.

GRAND PRIZE.—Times-Review, June 14: Mill is now working some tribute ore from the old chloride stopes. As soon as it is worked, will mill the company's ore.

ELKO CON.—Drift No. 4 has been advanced 13 ft the past week. The formation is hard syenite. Will cut the west lateral vein within a distance of 10 ft from the present face of drift.

NAVajo.—Good progress is being made above and below ground. The new boilers will soon be in place and other improvements will be completed as soon as possible.

BELLE ISLE.—North drift, 450 level, has been extended 88 ft; progress during the past week 15 ft.

ARGENTA.—Stopes producing some good ore, but the ledge is small. Shipped crude bullion valued at \$9,500.

Tybo District.

SOON START.—Belmont Courier, June 16: It is expected that the Tybo mill will soon start up on ores from the 2-G mine.

White Pine District.

HAMILTON NOTES.—White Pine News, June 16: The Smoky mill started up again on the 8th instant, and everything is running smoothly. They have put in a large new whistle which is as sonorous as a foghorn. A small force of miners has been put to work on the Edgar mine, two men on the Mammoth, and several others are at work at other mines on the hill. Austin Jacobson is taking out some fine ore in the Konigsberg. It is chloride, black metal and galena and will go \$300 to the ton. Capt. Drake expects instructions daily from London to resume work with the Burleigh drills in the tunnel. Our town wears an air of prosperity and people seem contented and in better spirits than for years past. Four dollars per day is paid for underground work by the Eberhardt and Sweetwater companies. Italians are mostly employed around the mill, who get \$3 per day.

ARIZONA.

THE OUTLOOK.—Prescott Courier, June 16: The so-called "mining outlook" is now very encouraging in Arizona. Here in Yavapai county, the mining industry, as far as carried on, is more successful than at any previous time in our history. We have the Howell reduction works sending out two or three tons of bullion daily; the Copper Mountain works; the Black Warrior mill; the Tip Top mill and many others. The Peck is being put in condition to produce bullion. Callen's Walnut Grove mill will commence crushing Monday next. We might mention other works, but have named a sufficient number to let people know that it is not all talk and no silver. In addition, considerable rich ores are being sent east and west for treatment. As Mr. Douglass, the great copper man, has arrived and was, yesterday, in Cop-

per basin, examining C. C. Bean's properties, we may set it down as a fact that furnaces will soon be running there, too, as well as at the Eureka mine, in Black Hills. Persons who are acquainted with mines owned by the Callen Co., in Walnut Grove district, express confidence in the result down there. The Josephine, at a depth of 70 ft, has 5 ft of gold bearing rock, which will yield, by mill process, at least \$40 a ton. The mine has a streak of free gold rock which is as rich as any ever before seen in this land of metallic wonders.

PINE SPRING MINE.—Arizona Miner, June 16: On Thursday evening, June 7th, Gavin & Co. had sunk 15 ft on their great bonanza, and at that depth the ledge showed better than on the surface some 30 inches of ore showing itself near the hanging wall. Of this 10 inches is fully \$15,000 ore, while the remaining 20 inches is \$1,500 value. At the present writing \$50,000 have been taken from the mine, with every indication of permanency. The walls are now solid and smooth, dipping at an angle of 45°. Many people thought that the owners were off, because of having refused \$150,000 for this property, when there was but a hole of 5 ft sunk. It now transpires, however, that they were wise in refusing the offer, for, let the mine turn as it may, they have out \$50,000 and \$100,000 in sight; hence they can't lose, but have a fair prospect of getting millions. Since the settlement of Arizona commenced no such find or strike has been made as that of Gavin & Co. The ore is marvelously rich and the vein unusually large for such high grade vein matter. The extensions are being worked, showing the same decomposed material as is found in the original discovery, and the probabilities are that good ore will soon come in.

SILVER KING.—Final Drill, June 16: The town of Silver King is booming and many people are pouring in. On the Monarch of the Sea they now have a tunnel of 200 ft. From the crosscut they have obtained first-class ore. Sinking will begin next week. The Silver King Co. is building an office at the mine. They are sinking the main shaft and are striking for 1000 ft; they are now making a station at 800 ft.

COLORADO.

MONARCH DISTRICT.—Cor. Denver Republican, June 16: Work has again been resumed on the Oshkosh. This excellent property is but a short distance from the town, and of such easy approach that, at a small expense, its ore can be directly loaded upon the cars. Discovered in 1878, it remained in possession of its locator till the following year, when development began, which has at intervals been continued up to the present time. After the discovery of the ore body was made, a tunnel of 135 ft was run, and ore taken out in sufficient quantities to prove beyond a doubt that the mineral existed in a large and well defined body. Mill-runs show returns of \$34 per ton, net. The property is now patented, and will be hereafter steadily worked. The owners intend to be ready for regular and continued shipments as soon as the railroad reaches the camp. Among other improvements and additions to the facilities of the town may be mentioned the saw mill, lately erected and in operation about a mile above town and at a point below a fine growth of timber, composed of white pine and spruce. The marble discoveries on the northwest side of town will be opened up for quarrying in a very short time. Such development as has already been done shows this new and valuable property to be of great extent and the quality has been pronounced by experts to be of very fine and beautiful character. So far the full extent has not been positively determined, but even at the present time such a large body has been uncovered as to warrant the employment of labor for the full development of it. Work upon it will be commenced in a short time, and a further and more comprehensive description will be then made in future communications. Although shipments of ore are being made, still considerable is accumulating on the ore dumps and in the ore houses, awaiting the arrival of the Denver and Rio Grande road.

CALIFORNIA MINE GOLD RETORT.—Register Call, June 16: W. J. Lewis brought up from the mills of the California mine company in Black Hawk to-day 200 ounces of gold retort cleaned up the past two weeks from 100 stamps. The output of this splendid property in milling and smelting ore is yielding \$25,000 per month. Sinking in the main shaft is being continued. It has attained a depth of over 1,400 ft—the deepest mine in the State of Colorado.

SPLENDID RETURNS.—The California mine company's production of mill retort from last week's run aggregated 382 95-100 ounces gold, 100 stamps running. The several retorts having a currency valuation of \$5,112. The quality, quantity and richness of the ore does not diminish as depth is attained the best mill dirt coming from the lower workings. The California mine company have the pluck and backbone to continue deeper developments, and they are to be congratulated in meeting with the success that is rewarding their capital and labor.

MONTEZUMA.—A postal received from A. Wettstein, from Montezuma, Summit county, last evening, states that snow storms on Collier mountain, where he is working, are of daily occurrence. He advises miners not to come of there just at present, as very little development work can be done at this time. The St. Johns company are trying to make arrangements with the railroad company for shipment of ore to the Denver smelters on a reduced basis of rates. Should they prove successful, the company will put 60 miners at work near that place. With more favorable weather for mining and prospecting, business of all kinds will increase.

IDAHO.

WOOD RIVER ORE AND BULLION.—Times, June 16: A freight train, of seven cars, left Hailey for Omaha yesterday forenoon, and another was to leave for the same place about five o'clock this afternoon. The train that left yesterday morning took three carloads of bullion and two of ore for Omaha, one of brick for Shoshone, and one of miscellaneous freight for way points. The ore and bullion cars went direct to Pocatello, and on to Omaha. Ore and base bullion are now arriving at the depot at the rate of about three car-loads a day, on an average. As the weight taken on each car is between 12 and 15 tons, it follows that the daily yield of ore and bullion at present is about 40 tons. This is a very small yield, to be sure; but it must be borne in mind that the high freight tariff—\$30 a ton to Omaha—has prevented

mine-owners from selling any ore except such small quantities as were required to procure the wherewithal to pay running expenses. Since the reduction of rate to \$27 per ton, however, (which was announced yesterday) the miners have doubtless determined to make more liberal shipments, and it is probable that, within two weeks, the shipments will average at least 60 tons per day.

OUR POSSIBLE ORE YIELD.—Wood River, June 16: Careful figuring, based upon measurements of the ore bodies now thoroughly opened by drifts and winzes, and ready for the drill and pick to extract from the mine, show that according to the rate of each man's work so far in taking down ore, there can be the following lots extracted regularly per month from the mines named below, as soon as the mine owners desire to make shipments. The amounts given are approximated from the daily product and placed in the aggregate as monthly shipments for better understanding of the shipment facilities required. Here they are: Mayflower, 500 tons; Bullion, 500; Jay Gould, 300; O. K., 240; Ophir, 150; Rough and Ready, 75; Mountain View, 75; Idahoan, 240; Eureka, 300; Valley View, 150; Point Lookout, 150; Parnell, 75; Chicago, 75; Total, 2,830 tons. As will be seen at glance only mines at Bullion, or in the immediate vicinity of that town, are mentioned. If Deer Creek, Warm Spring Creek, the mines around Bellevue, on the East Fork and elsewhere be taken into consideration, it will be generally admitted by all who understand the matter, that the figures above given can be readily doubled, and the yield thus brought up to 5,660 tons per month. This yield cannot be expected now, however, owing to the high freight rates; but with lower rates the product would soon reach the quantity stated.

ROCKY BAR AND ATLANTA.—Cor. Bellevue Star, June 16: The Ada Elmore mill is running, and also a 10-stamp mill below town. These two mills, and the mines from which the ore is extracted, give employment to about 100 men. One hundred and fifty men are at work at Atlanta, and there are many more who are idle and will not be employed till the wagon road is open to Rocky Bar, which will not be for three weeks yet. Grading for two of the new mills at Atlanta has commenced, and teams are in demand. The mines are now looking first rate, and very lively times are anticipated.

MONTANA.

PHILIPSBURG.—Inter-Mountain, June 16: The Philipsburg mining district, which for some years has been resting on its laurels, and in which very little deep development has been going on lately, has entered upon a new lease of active life and is having a genuine boom. This fact is owing in a great degree to the recent developments on the Granite Mountain in tunnel No. 2. The tunnel has a total length of a little more than 1,000 ft. The rich pay ore was first encountered at a distance from the face of about 900 ft from which point the ore has preserved a uniform width of three ft, increasing in many places to five for a length of 130 ft. This shoot as far as explored samples 300 ounces, though much of its product assays considerable more than that. Within a few days 500 tons of \$500 ore will be shipped to Cheltenham, near St. Louis for reduction in the Harrison works.

NEW MEXICO.

NOTES.—Los Vegas Gazette, June 16th: The Iron King mine at Kingston is improving with every day's work. Recently it has been put in a good condition for stoping. The large amount of travel on the Silver City & Deming road indicates an unusual activity in the mines of the interior of Grant county. Tinhorn capitalists are not thriving in New Mexico to-day. Miners have learned to size up a man's pile before entering into any extensive negotiations. The Superior and Bullion never gave greater promise of permanent value than they do to-day. The camp of Kingston may be depended upon. All the mischief in it has disappeared. The mines about Fleming are yet the wonder of the world. Whoever heard of a \$500,000 property being paid for out of the workings from the grass roots down at the rate of \$75,000 a month, as is the Old Man. Machinery is being erected at the Cash Entry mine in the Cerillos.

CARLISLE GROUP.—Southwest Sentinel, June 16: The owners of the Carlisle group of mines in Steeple Rock district, have made arrangements to develop the properties. The group is comprised of the Center, Pennsylvania and the Star of the West. Work will be pushed with earnestness and vigor. Judge A. S. Potter we learn will superintend the workings and select a place where ground will be broken. Should the owners meet with their anticipations in striking large bodies of mineral, it will take considerable coin to purchase the properties. The Carlisle lode is absolutely the finest looking mine in the great Southwest. The Thicket mine, two miles north of Brennen's 76, is proving to be a very valuable property. The main shaft is now down 85 ft and has 300 tons of first-class carbonate ore on the dump. The rock assays all the way from 20 ounces to 670 ounces in silver per ton. The formation and contact is about the same as that on Mr. Brennen's celebrated mine, and there is no doubt but that when as fully developed it will prove to be equally as good property. The mine is owned by Samuel Eckstine, Messrs. Learned, Roach, and Stevenson.

OREGON.

MINING NOTES.—Jacksonville Times, June 16: A prospector has found a promising silver ledge near Ashland. Klippel & Keaton are digging a new ditch to bring water on their Poorman's creek diggings. Wm. Selph and Mr. Cole are now prospecting for quartz in the Blackwell district and are sinking a shaft at present. Thos. Chapman, of Josephine county paid Jacksonville a visit Monday, from whom we learned that the season is at an end with most miners. Considerable mining is being done near the mouth of Beaver creek, in the Siskiyou mountains. Patterson Bros. have a hydraulic in operation there, DeLamater & Newman, who own first-class mines near Kerbyville, have cleaned up. They made a satisfactory run, although water was not as abundant as usual. D. Steckel, of Wolf creek called this week as usual. He informed us that the Portland Co. by whom he is employed washed off a large piece of ground that is now being cleaned. Crushing has been suspended at Welch & Ross' mill in Willow Springs precinct, owing to the scarcity of water. About three tons of rock from the John Roten ledge on Kane creek was crushed and prospected even better than anticipated.

Have Your Claims Patented.

That we, as a mining community, are on the eve of new conditions, cannot be denied. The incoming of the railroad with its revival of old interests and the creation of new ones, will enlarge, change and modify present business relations largely, and give strength and impetus to long flagging powers. With an increase of business there will naturally be a clash of interests. A new race of men will follow the track and spread themselves throughout the mines. Among these will be numbers with whom might makes right; others, keen-eyed, shrewd and bold, will discover defects and take technical advantage of such shortcomings. The history of every mining camp on the coast has been one of contention, litigation, violence and fraud, in the matter of the settlement of the mining titles. Titles that seem perfect now, because they pass unquestioned, will assume a different aspect when subjected to the critical test of legal investigation, or perhaps submitted to the decision of an unlettered jury, whose minds are swayed one way or another by the eloquence or chicanery of lawyers. "In time of peace prepare for war," is an ancient adage. Patents that may now be obtained with ease, will be rendered more difficult in time, when the county becomes full of aggressive, active men thirsting for wealth and determined to war for it at every possible point. One man will not be allowed, peacefully and unquestioned, to hold dozens of locations, from year to year, unworked and unpatented. With or without right, these claims will be invaded, "jumped," and possession held at the mouth of the shotgun, unless the owner can show a clear and perfect patented title to it. This state of affairs is bound to come. The easy-going, indifferent conditions now existing, cannot always last. Now, therefore, is the time to make application for a patent to secure perfect and undisputed patent title to those claims which are deemed of sufficient value, and any claim that is not worth the cost of a patent, is valueless for any purpose whatever. A patent fixes definitely, for all time, the question of ownership, and places its holder above the reach of blackmailers, who ever lie in wait to assert a claim to mining property when it is approaching a sale. Capitalists are loth to invest money in claims that are unpatented. They have had a hard and bitter experience in the purchase and holding of mere locations, and are seldom tempted to invest in them unless they discover some unusual merit, for which they are willing to take the chances. The experience yet to come to our miners will demonstrate the truth of this statement.

Already have we heard of two individual cases where property in this county could have been disposed of for most respectable sums, had the same been perfect in title. One thing is certain, that no man able financially to purchase a mine, will do so as long as there is a cloud hanging over it. Lawsuits can be more easily obtained than by being bought. It is safe to say that many a one who now rests in financial security as to title, will be surprised in the future to find that when he is about to realize upon his property, that he is balked by an "outstanding title." This can hardly fail to be the case where there have been so many locations and re-locations made, running through a series of years, and the question as to the legality of re-locations resting in the mouths of men who, for a valuable consideration, may remember this or that state of facts. We cannot state this necessity too strongly or argue the matter with too great a force. We know what the future must develop, and we warn and admonish the holders of mining claims that this is the acceptable time for obtaining patents to their ground. We do not desire to prophesy evil, but the logic of events point in the direction we have spoken of. We cannot hope to escape the dangers, vicissitudes and experiences of other places, situated as we are. Human nature has not put on many changes recently, and this climate has no elements to repress and hold back the grasping spirit of men to whom gold is a God.—*Ingo Independent.*

RUNNING BY WATER POWER.—Everything being in readiness the water was turned on at the Idaho mill on Friday afternoon, and has since been going without interruption. The change of connection from steam to water was made in less than an hour, which was speedy work. With 70 inches of water under 450 feet pressure 35 stamps are driven with ease, and as satisfactorily as done with steam. The wheel used is the Pelton, 6 feet in diameter, and it is found that over 90 per cent of the power of the water is obtained, or as much as was shown at the experimental trial of the wheel made several weeks ago. The water power connections for doing the hoisting and pumping will be completed within ten days.—*Grass Valley Union.*

CARSON AND COLORADO RAILROAD.—The end of the track is six miles south of Chrysopolis, and within eight miles of Independence. Within a week it will be at Hawley, on Owens lake, about four miles south of Swansea, and directly opposite Cerro Gordo district, which is distant about five miles. Hawley will be the temporary terminus and will be a very important station. In addition to Cerro Gordo, Darwin and Panamint, situated respectively twenty-four and fifty miles east, will receive their supplies through this point. A number of mines in these districts will resume work, and a great deal of business will be done this summer.

The Grain of Wheat.

Even in the hurry of harvest it will be well to pause a moment to consider the structure of a grain of wheat. It is seldom, however, that we do stop from our hurried work to think of the material we are handling. Rather is the golden grain treated as we would sand or gravel, merely with a thought of its market value. But the kernel of wheat is an interesting study. A grain of sound ripe wheat in itself, is a small thing; but let us examine it and see what it contains. In form it is nearly egg-shaped, with a longitudinal groove on one side; if we sever it horizontally the sections are heart shaped. The accompanying engraving, showing a longitudinal section of a grain of wheat enlarged sixteen diameters, gives a clear idea of its structure. The outside layer or cuticle is mainly composed of silica—the mineral base of sand—which is rendered soluble by potash in the soil, and is carried by the little veins of the wheat plant and deposited with the woody tissue. The bran consists, first of the epicarp (1) or outer coat of longitudinal cells; next the mesocarp (2) or inner coat of longitudinal cells; and the endocarp (3) or the coat of transverse cells. This triple coat, while indigestible to man, (yet highly relished and valuable as cattle food,) is perfectly adapted by nature for the reproduction of the plant, performing the function of circulation for the seed, without which it could not develop a new plant, or even germinate. At the upper end of the kernel is seen an appendage, consisting of minute filaments, or hairs, that are absorbents of moisture in the earth, and which convey it to the outer coats, and thus perform an important office in aiding germination.

Returning now to the coats of the grain, No. 4, is the epispem, or outer seed coat, and No. 5, the tegmen, or inner seed coat, which contain a substance called cereoline. No. 6 is the per-

The Wheat Grain Analyzed.

isperm—a single layer of large cells filled with gluten and nitrogenous products, the most nutritious portion of the grain. Pure gluten is, for the most part, composed of proteine, a substance which forms the basis of the nitrogenous compounds, albumen, fibrin and caseine, besides sugar, gum and soluble albumen. (Gluten is not, however, limited entirely to this layer (No. 6), as it is found distributed through the interior of the berry, as well as in the bran. No. 7 is the endosperm, or large cells, which form the central portion of the berry, consisting mainly of starch in minute granules.

The phosphates of soda, lime and magnesia are found about the center of the kernel, where the outer layer turns into the berry, forming an inner heart-shaped section. These are the bone and brain-making elements of wheat, and the greater the quantity that can be obtained or preserved in the reduction of the grain the more valuable is the flour.

The chit, germ, or embryo, is seen at No. 8, near the large end of the kernel, and in the crease. It is rich in gluten, and contains also starchy oil, etc. Over the germ is a thin scale-like pellicle, easily removed with the thumb nail, revealing the little germ containing oil beneath.

While the illustration and description given show what the general structure of a grain of wheat is, it must not be supposed that the gluten and the starch are strictly defined layers. They are mingled together, the gluten largely predominating towards the bran, while starch forms much the largest portion of the center.

Nature's provisions for the perpetuation of vegetable, as well as animal life, are perfect; her laws are harmonious, and at the same time inexorable. She requires perfect conditions if the highest results are to be obtained. In the degree that such conditions are present, will be the measure of excellence found in each and all of the myriad forms of life that abound on the earth. In a grain of wheat, nature furnishes the constituents required by the delicate plant that springs from the germ under the friendly influence of moisture and warmth in soil, and supplies to both the radical and the plumule, the populum necessary to their existence until they

have gained sufficient vitality to lay hold of the food she also supplies in the earth and the atmosphere for the growth and maturity of plant life.

Nevada and Her Merits.

The State of Nevada is under a temporary cloud; but there are some things about it which must not be forgotten; some things, says the Salt Lake Tribune, which sharp business men should always keep in sight. It has not yet been a State 20 years; it has never contained more than 65,000 people; it has been discriminated against and robbed by transportation companies as no State ever was before; but it has yielded more gold and silver, and paid more dividends from its mines than any other three or four States and Territories combined, except California. Its people have purchased from other States and Territories more material than the same number of men ever purchased in the same length of time. And it has paid in gold and silver for all it has bought. The bullion of Nevada, between 1860 and 1864, acting as a lever in the national finances, did more to uphold the credit of the country than did the product of the most powerful Eastern State; and because of that product and the product of California and these interior Territories, those in power had the material with which to meet the country's interest obligations; the courage to commence to pay the mighty debt, and finally to bring about redemption and a reduction of 50 per cent in the rate of interest. A State which has been so important, which still remains with but two or three exhausted mines, and with plenty of others which have never yet been any more than surface-scratched, should not be dismissed with a sneer. It must be borne in mind, too, that a great many of the camps of Nevada have been worked from 100 to 250 miles from the railroad, and that when the railroad was reached the fare was eight cents a mile and freights were in the same ratio. Nevada has no terminal points, and hence it costs three times as much to send anything to any point in Nevada as it does 300 miles further east or west. If under such circumstances Nevada has been made to pay, there must be some unusual merit in its mines, and the promise of what it is to accrue to the first railroad that penetrates its southern districts is a matter which sharp railroad men should keep in mind. Its gold and silver is not its only minerals. We of this place are rather proud of the fact that by evaporating the water from six or seven barrels filled from Salt Lake there remains a barrel of salt. In Southern Nevada there is a mountain of solid salt, from which the moisture was long ago evaporated, and it is as white and pure as the cleanest Eastern table salt. There are besides vast beds of iron, borax, gypsum, sulphur, copper and other minerals which are more used than either silver or gold. And two-thirds of all that region of more than 90,000 square miles is naturally tributary to this city. If none of the existing railroads are ready to begin the work of extension in that region, the men of this city should commence a narrow-gauge road to the southwest. One million of dollars would build the first 120 miles. This could easily be mortgaged for enough to build 120 miles more. That much road would command Deep Creek, Osceola, Pioche, Bristol, Ward, Taylor district, White Pine, Reville, Hot Creek, Tybo, Belmont and as many more smaller districts, all of which want cheap machinery, cheap fuel, cheap labor and cheap supplies of all kinds. Twenty per cent. on the cost would be \$400,000 per annum, or a trifle over \$1,000 per day. Ten car loads of freight at \$10 per ton and 20 passengers per day at three cents per mile would be ample to pay expenses and give to the owners 10 per cent. on their investment. The truth is, such a road would at fair rates pay for itself, clear of expenses, once in every three years. Our sharp men should make a note of these facts, and the holders of real estate should not forget that the road, if built, would have the effect to just about double the real value of their property.

USEFUL NOTES ON WATER.—One gallon of distilled water weighs ten lbs.; one gallon of sea water weighs 10.32 lbs.; 1.8 cubic feet of water weighs 100 lbs.; 36 cubic feet weigh one ton, equal to 224 gallons; one cubic foot contains six and one-fourth gallons. [The English standard, or Imperial gallon, is here referred to.] The average daily consumption of water in towns is 16 to 20 gallons per head. In pipes, the square of the diameter in inches equals pounds weight of water per yard. Example: An inch pipe holds nine lbs. per yard. One hundredth inch of rain is about one ton weight to the acre. A nominal horse power for a boiler requires one cubic foot of water per hour. Circular apertures are most effective for discharging water, since they have less frictional surface for the same area. The vena contracta is the best form of orifice for discharging water. The ordinary speed to run a pump is 80 to 100 feet per minute. The pressure in pounds per square inch of a column of water is the height of a column in feet multiplied by 5.34, or, for an approximation, one-half pound pressure per square inch for each foot of height. Water, in flowing through an aperture, has a velocity equal to that acquired by a heavy body falling freely from a height equal to the distance between the center of the aperture and the surface of the water. Doubling the diameter of an aperture increases the flow four fold.

Campo Seco Copper Mine.

The village of Lancha Plana is situate some fourteen miles southwest of Jackson, and on the north bank of the Mokelumne river. While its variegated resources, consisting of deep gravel mines, coal and copper lodes, are still excellent, cozy cottages, surrounded by productive orchards, gardens and grain fields, greet the eye. Numerous abandoned reservoirs for water, now filled level with the debris of the horrid hydraulic miner, yield continual fat crops of alfalfa and clover. In the absence of a hotel, the weary traveler is pleasantly entertained by Mr. J. Maroon and lady, with all the home comforts that pertain to intelligent farm life.

Crossing the river on a suspension bridge, a short distance east of the village, a well graded wagon road leads to the Campo Seco Copper mine, distant one and one-half miles. The matrix of the vein is slate; course, west of north; dip of vein, east, at an angle of about 60°. The incline is 200 feet deep. The ore in the lower level reaches twenty feet in lateral extent and has been stoped about seventy-five feet in a linear direction. A three foot Knight's wheel with sixty foot pressure gives the motive power for hoisting and a four-inch (arrat's) plunger pump. Some 800 tons of assorted ore were shipped to San Francisco. The low grade residue on dump, some 700 tons, are now being worked at the company's reduction works, a short distance below the mine. The reduction works were substantially constructed to reduce copper ores by M. B. Dodge's methods and patents. Soda, obtained from gas works, is mixed with the ore and then fed to the rock-breaker. Thence a pulverizer receives the ore, discharging it through a screen. The screenings are carried upwards by a belt, to which buckets are attached, dumping the material into a hopper which feeds the revolving roasting furnace. This roaster is a huge cylinder, 28x8 feet, making two and a half revolutions per minute. The cylinder weighs some twenty tons and when lined inside with fire-proof brick and in operation, about fifty tons. A brick furnace under the upper end of the cylinder, which is slightly inclined from the horizontal, supplies the heat required for roasting. At the lower end a continual stream of pulverized, roasted ore is discharged, thence passing to the leading vats, and ultimately to precipitating tanks. A heater supplies the vats with steam. The rock-breaker, pulverizer and revolving furnaces are propelled by a four and a half foot Knight's wheel with a pressure of 160 feet. The works have a capacity of reducing twenty tons of ore in twenty-four hours. Mr. C. Berger is superintendent.

Wallace, the eastern terminus of the San Joaquin & Sierra Nevada railroad, is within six miles, westerly, of the mine. This belt of copper lodes extends northerly through a portion of Amador, and southerly through Calaveras. I was shown fine specimens of copper ore and native copper, taken from the extensions of the above mine years ago, but the pursuit was abandoned on account of the then low price of copper.—*Cor. Amador Dispatch.*

The Violin.

We have recently examined a violin made by C. W. Powers, of this city. The wood of the top is about forty years old, and was taken from the broken spar of a sailing vessel; the back of the violin is of fine Eastern maple, selected by White, the well-known violin maker of Boston—the whole being put together and finished in a masterly manner, showing unusual skill in mechanism and acoustics. Judging from its tone it would bear comparison with many a reputed "master."

The violin has come to be looked upon by many connoisseurs as a fathomless, complex scientific problem. Indeed, it is little understood, mainly because no practical knowledge can be gained from books on the subject. Its unprofitableness as a study prevents it being generally pursued by those devoted to studying dead arts, and it would seem destined to remain shrouded in mist. To the theorist, a lack of knowledge only lends an additional charm and fascination, to the already entrancing effect of the "magic wand" in the hand of the skilled artist.

There are several amateurs in this city who display considerable skill in the construction of the violin. An hour is well spent in the workshop of Captain D. C. M. Goodsell. Having had ample time and means, he has applied himself assiduously to this pleasurable work, for the past twenty years, not a day passing that he has not given it some attention. During that time he has gained much knowledge relative to sound, and its distribution in the violin. A "chef" would hardly escape his eye unrecognized, yet his knowledge is likely to remain with him—and the same can be said of Genunder, of New York, and others, unless they choose to transfer their deductions upon paper, for the benefit of those to follow them.

Science, as well as time, has demonstrated that the wood in violins needs to be protected by varnish; not alone from dampness, but natural decay. The oil of varnish penetrating the wood and leaving an elastic, outward surface, arrests that decay as nothing else has been shown to do, and with age mellows and intensifies the tone vibrations—a fact which is often overlooked, or disregarded. Proper varnish is necessary, however, for this result; the finest varnish even, used in manufactories will not do for this purpose. Much more might be said to interest the lover of the violin in this "far" western coast, but for the present this must suffice.

Sierra as a Mining County.

Ever since 1850, Sierra has ranked, says the *Sierra Tribune*, among the very richest mining counties of the State. Of course there is no means of ascertaining the annual yield of the mines of this county since that period. Were we able to present such statistics, the figures would not only verify our assertion, but would even astonish old Californians, familiar as they are with stories of the immense wealth which has been unearthed amid the ridges of the Sierra Nevada. From the period mentioned this region has been occupied by a large population of hardy miners, who have not only found profitable employment in the river beds, ravines and hills embraced within the area of the county, but many of them have retired as millionaires from the hard labor of mining, or else entered into mercantile or other more profitable pursuits. There are prosperous merchants and bankers residing and doing business in the county now, worth their tens of thousands of dollars, who came here poor men and made the foundations of their fortunes by hard labor with pick and shovel. Instances of this character are so numerous that the conclusion becomes inevitable that Sierra county has afforded the most profitable field for mining labor in the State. And what it has been in the past, it still is. The main wealth of this country remains as yet untouched in gravel deposits, deeply imbedded in the hills, and in quartz lodes which traverse almost every mountain's side. It certainly requires much patient and almost superhuman labor to develop the gold deposits of these hills, but the labor is being applied, and will yet be applied with still greater force. The rich hill diggings of Fir Cap, Howland Flat, Gibsonville and Port Wine and vicinity, have not been surpassed by any in the State, and they still promise to yield vast stores of the precious metal for years to come. The quartz interest of this section, yet in its infancy, is attracting the attention of capitalists abroad, and will soon loom up in gigantic proportions. Comparatively speaking, but little has been done toward developing this interest, yet the enterprises of this character, which are being prosecuted, have proved remunerative in the highest degree. This interest is sure to be of great importance to this county at an early date, and will form a solid basis of permanent prosperity. When the facts to which we allude become more widely known, a new industrial population will be attracted hither, and the business and prosperity of Sierra county will again loom up, rivaling the palmy days of the past.

Queer Ore.

A knowledge of mineralogy obtained from the books is very good as far as it goes, but practically it does not go very far. More than this, in this country of ours of a thousand and one singular formations, the miner, experienced in every day work, stumbles frequently upon rock the character of which he can tell no more about than if he had never mined a day in his life. A case in point happened the other day at the Eureka Con. reduction works, at which tribute ores and simple lodes are received from all over Southeastern Nevada. Some ores had come in from Reveille District, Nye county, some 60 miles southeast of Tibo, and from Morey, which no miner in this district would stop on the hills to look at for a moment. The rock from Reveille especially seems wanting in every aspect of what is called ore in these parts. To use Bob Zeile's expression, it looks like a mixture of lime and brick-bat. But this very stuff, some six tons, was tested and found to average over \$2,000 per ton in silver and gold, chiefly the former. Some experts came down to the works and Uncle Zeile showed them the pile from which an assay had been made, with the remark: "What do you think of this sort of stuff? I don't think there is anything in it." They all agreed with him, of course, and went away with the impression still strong in their minds that what they don't know about ore is not worth knowing.—*Eureka Sentinel*.

THE FRESNO FOOTHILLS.—"Vic," a correspondent of the *Chronicle*, writes as follows from Coarse Gold Gulch: Along the eastern boundary of Fresno county, or that portion embracing the foothills of the Sierra Nevada mountains, lies a region of undiscovered mineral wealth and agricultural possibilities, neither of which have received any great amount of attention. The early influx of prospectors to the coast brought its pro rata of the "pick-and-pan" brigade to this isolated region. An honest and dishonest, shrewd, keen-witted mob, they came and went, leaving monuments of their industry along gulch and ravine in heaps of gravel and sand. There is now some fine gold being sluiced and rocked, and occasionally a nugget of considerable value is found. The outcropping of the quartz, in many places gold-bearing from the surface, is almost continuous from the Fresno to the San Joaquin river. A few quartz mills of small capacity are being run upon ores already extracted. Many horse arrastras are running with good success, but unless the ores thus worked are of great richness nothing but a living results from this mode of reduction. Thus the mineral wealth of Fresno county is still an unknown quantity and awaits an investment of capital.

USEFUL INFORMATION.

Ancient Mortar.

In examining the other day, says a contemporary, the remains of Old Sarum, an old Roman fortress in the south of England, near Salisbury, we were surprised at the remarkable strength of the mortar by which the flints and sandstones were held together. We find the mystery explained in the following paragraphs from an authority on the subject:

"The ancient masons were so very scrupulous in the process of mixing their mortar that it is said the Greeks kept ten men constantly employed for a long space of time to each basin; this rendered their mortar of such prodigious hardness, that, *Vetruvius* tells us, the pieces of plaster falling off from old walls served to make tables.

"It was a maxim among the old masons to their laborers that they should dilute the mortar with the sweat of their brows; that is, labor a long time, instead of drowning it with water to have it done the sooner.

"The weakness of modern mortar, compared to the ancient, is a common subject of regret; and many ingenious men take it for granted that the process used by the Roman architects in preparing their mortar is one of those arts which are now lost, and have employed themselves in making experiments for its recovery.

"But the characteristic of all modern artists, builders among the rest, seems to be to spare their time and labor as much as possible, and to increase the quantity of the article they produce without much regard to goodness; and perhaps there is no manufacture in which it is so remarkably exemplified as in the preparation of common mortar."

ANALYSIS OF THE ORANGE.—The *Boston Journal of Commerce* publishes the following result of the analysis of a medium sized orange, purchased in Faneuil Hall market: The skin weighed 67.5 grams, which is 23.33 per cent. The seeds weighed seven grams, which is 2.84 per cent. The pulp weighed 182 grams, which is 83.83 per cent. The skin contained in 100 parts: Water and volatile oil, 78; organic matter, 21.30; ash, .64. The seed contained in 100 parts: Water, 50; organic matter, 48.64; ash, 1.36. The pulp contained in 100 parts: Water, 90.90; organic matter, 8.68; ash, .42. The pulp contained in 10 parts: Grape sugar, 4.3; cane sugar, 4.2; in free acid, 1.5. The free acid consisted of about equal parts of malic and citric acid. The ash constituents of the orange were as follows: Potash, 38.7; soda, 7.6; lime, .23; magnesia, 6.5; ferric phosphate, 1.7; sulphur, 2.9; silica, 6.2; phosphoric acid, 13.4. A gentleman in Manchester claims to have succeeded in applying orange peel to a very useful purpose. Orange peel dried in or on an oven until all the moisture has been expelled becomes readily inflammable, and serves admirably for lighting fires or for resuscitating them when they have nearly gone out. Thoroughly dried orange peel will keep for a long time, and might be collected when the fruit is in season and stored for winter use.

PROTECTING IRON FROM RUST.—A new process for preserving iron is described by *Les Moutres*. It consists in treating the casting with dilute hydrochloric acid, which dissolves a little of the metal and leaves a skin of homogeneous graphite holding well to the iron. The article is then washed in a receiver with hot or cold water, or cooked in steam, so as to remove completely the chloride of iron that has been formed. Finally the piece is allowed to dry in the emptied receiver and a solution of caoutchouc, gutta percha or gum resin in essence of petroleum is injected and the essence afterward evaporating leaves a hard solid enamel on the surface of the iron work. Another plan is to keep the chloride of iron on the metal instead of washing it off, and to plunge the piece into a bath of silicate and borate of soda. Thus it forms a silico-borate of iron, very hard and brilliant, which fills the pores of the metal skin. As for the chlorine disengaged, it combines with the soda to form chloride of sodium, which remains in the pickle.

THE FUTURE OF THE COTTONWOOD.—The despised cottonwood may yet become the most popular as well as the most valuable tree. Late inventions and discoveries have revealed the fact that the finest polish and strongest household furniture can be made out of paper. It can be pressed so hard that no instrument short of a diamond can scratch it, and it can be given the finest shades in imitation of wood, and produced cheaper than walnut, mahogany or ebony. And late discoveries in paper making establish the fact that cottonwood makes the whitest and strongest fiber pulp yet manufactured out of wood. There are vast quantities of pulp imported, and some newspaper men are clamoring for it being done free of duty. Paper mills in Delaware, Pennsylvania, and other Northern States, are shipping thousands of cords of poplar wood from the Chowan river in North Carolina, one mill in Delaware contracting for 30,000 cords.

HOW TO TEST FLOUR.—In testing flour it is always a good sign to have a yellow tint, but if it is very white with a bluish tint it is not so good, because it lacks the gluten. Next examine its adhesiveness by wetting it and kneading it between the fingers. If it works dry and

elastic it is good; if it is soft and sticky it is poor. Flour thrown against a dry, smooth, perpendicular substance, such as a board, will show whether it has life in it or not by adhering in a lump, or, if after squeezing it in the hand, it retains the shape from pressure, it is a good sign. Gluten will turn red if cochineal is applied in a thin solution, so that a person can easily tell how large a quantity of gluten there is in wheat by using cochineal.

THE GLUE POT. There are a great many times, truthfully says one of our contemporaries, when a glue pot in the house is a "well spring of pleasure," and is an economical investment, especially when one of the kind here described. Buy at a tin shop one small tin cup, costing five cents, and a large one, costing about ten, in which the smaller one can be set; five or six cents' worth of glue will mend a great many broken articles, or will fasten the things that have become unglued. Put the glue in the small cup with a little water; put boiling water in the larger one, and set the glue pot in it; in a few minutes the glue will melt and be ready for use.

WATER-PROOF LEATHER.—E. Pollack has the following note on water-proof leather: The fat having been removed, the clippings are mixed with starch paste, some gum arabic, and one per cent of alum, and pressed into plates. It is then treated with a solution of soda soap, and pressed again. Thus it becomes impregnated with fatty aluminous compounds. Greased leather clippings are first to be treated with sodium silicate of caustic. The resulting soap is then rendered insoluble by impregnating with alum or zinc sulphate.

ETCHING LIQUID FOR STEEL.—Mix one ounce sulphate of copper, one-half ounce of alum, and a teaspoonful of salt reduced to powder, with one gill of vinegar and twenty drops of nitric acid. This liquid may be used for either etching deeply into the metal or for imparting a beautiful frosted appearance to the surface, according to the time it is allowed to act. Cover the parts you wish to protect from its influence with beeswax, tallow, or some similar substance.

TO PROTECT BRICK WALLS.—Bricks are very porous, and paint very expensive on such a surface. Still brick houses with unprotected walls are always damp after a protracted rain. A cheap preparation that would prevent the water from permeating the brick might be made by mixing a thin wash of Portland or Rosendale cement, with preference for the former. It may be applied in the same way as whitewash.

PAINT FOR KITCHEN WALLS.—For a paint or varnish suitable for kitchen walls, that will wash or can be cleaned in some easy manner, where the walls are not hard finished, use linseed oil paint, that is, any colored metallic oxide, graded in linseed oil.

GOOD HEALTH.

Fireside Chats on Health.

[BY HILDA DELESTHER.]

I noticed in the *SCIENTIFIC PRESS* of May 5th, the mention of a possible cure for neuralgia by the eating of raw oatmeal soaked in milk. If oatmeal taken in that way would keep the bowels open it might cure many aches and pains, for constipation brings on so many diseases. But the item I refer to reminded me of the directions given me by an experienced nurse for making oatmeal gruel for my sick boy.

"No, don't cook it much," said she, "the more you cook it the more binding it will be. Let it just barely come to a boil, then turn it out and take it up to him. Don't strain it, make him eat the meal and all if you want to cure constipation. I suppose he won't relish it so well when cooked so little, but then it isn't bad for a medicine, and anybody could get used to it so as to like it after a while, I reckon."

This was a new doctrine to me, for when I first learned about making oatmeal mush I was duly impressed by my teacher as to the desirability of cooking it two hours or more; so I supposed that half an hour for gruel, after it began to boil, was none too much. But now I think I have had some proof that mush is more healthy when cooked only half an hour. I wish some of your Scotch readers would tell me how it is prepared in Scotland.

Night Sweats.

A simple remedy for night sweats, which I have tried on more than one occasion, is the drinking of cold sage tea, a few swallows at a time, during the day and evening, and did not have to use more than one or two cups a day for a few days, before the cure was effected. This remedy was given me by a physician, but whether it would cure a case of long standing I cannot say, but think it worth trying.

Vomiting.

As the fruit comes on, if your children are taken with pains in the stomach by eating unripe or overmuch fruit, give them lukewarm water until they vomit. Or, if they are taken with vomiting, it is a sure sign that there is something in the stomach that needs to be thrown off, and the vomiting will often be stopped the sooner if you assist in the cleansing process by the free use of warm water, instead of being frightened and dosing them with all sorts of medicine to stop it. For several

years I never gave my children a drop of medicine; sometimes they would ask for the drink of warm water or a wet compress at night, if they felt unwell. Of course I paid attention to their bathing and tried to give them plain good food to eat, at regular times. The vomiting of infants is often caused by too frequent nursing. Nurse or feed them once in two hours for the first two weeks, then once in three hours; then, if they cry, you may know it is not because they are hungry. I am sure they are sometimes misused, when their stomachs are already overloaded, just because they cry.

Diarrhea.

When I was quite a small girl, I read that eating from three to six strawberry leaves would cure this disease, and after that if I was ever taken sick in that way, instead of complaining to my mother I used to gather and eat my strawberry leaves, and was very soon well again. Since coming to California I have used cultivated instead of wild strawberry leaves. I have met people who refused to eat green corn because it produced the same effect upon them as a dose of physic; but they would take the physic and suffer the consequences with all the equanimity possible. Let them try the green corn again. I believe they will find themselves the better for it.

Grape Cure.

I have heard several times about the grape cure as practiced in Germany, but can learn nothing of the method. I would be glad if any one knowing about it would tell us what disease it cures, and whether patients are allowed any other kind of food, or do they live on grapes alone? And do they swallow the skins or seeds of the fruit? California has such delicious grapes, let us make all the good of them we can.

Learning to Swim.

The great difficulty to the beginner is to learn to keep the proper position of the body after attaining it. This difficulty can only be overcome by using the proper stroke after having placed the body in the correct position.

In the use of the arms, the only direction that can be given is to remember that when the arms are thrust forward at the beginning of the stroke, such positions of the elbow and hands should be taken as will make the least resistance to the water. To accomplish this, the hands should be placed palm to palm, and the elbows made to come quite close together, starting them from under the chest. In making the effective part of the stroke, our object is to get a forward motion only. The arms and hands should be so placed as to produce the greatest resistance upon the water. To accomplish this, the palms of the hands should be thrown outward, and the plane of the direction of the stroke of the arms made parallel to the surface of the water.

The most important and the most often defective point in swimming is the mode of using the legs. It would be well for a beginner to observe the swimming of a frog, for undoubtedly the same method of using the legs should be adopted by man as is displayed in the model swimming of that amphibian.

In analyzing the stroke of the frog, we notice that there is no vertical motion; the whole direction of the force is in a plane exactly horizontal, and is accomplished by virtually opening and closing the space between the knees—offering the sole of the foot as a resistance while kicking, and placing the feet in a position of least resistance while recovering.

In accomplishing the first of these conditions—the opening and closing of the space between the knees—the knees should be thrown out, and the contraction of the legs made slowly, in order to cause as little resistance as possible to the headway already attained.

It will be found that, if we alternate the stroke of the arms and legs by giving propulsion with one while recovering with the other, a more constant buoyancy will be attained, and for long swims it will be found far less fatiguing.—*Popular Science Monthly*.

THE NOVEL-READING DISEASE.—Physicians are familiar with a complaint which, although sufficiently specific, has yet no name of its own. The patient suffers from an alarming and morbid thirst, and consumes a perfectly fabulous amount of fluid, almost always of an unwholesome nature. Tea, in a highly diluted shape, raspberry vinegar and water, soda water, or some other such abominable mess, is taken by the gallon, and the unnatural craving is stimulated by indulgence. Wholesome food is refused; no exercise is taken; and the patient finally sinks into a flabby and sickly condition, which nothing but severe and determined treatment will shake off. This dropsical habit of body finds its exact analogue in the species of mental dropsy, which is produced by over-indulgence in three-volumed novels. This terrible complaint is one of the worst evils which modern civilization has brought with it. Its progress is gradual, very insidious, and often almost imperceptible. At first all that is noticed is that the sufferer is apt to be found bent over a novel at unnatural hours. Soon, however, the disease becomes more pronounced, and in its worst stage novels are read through at the rate of three or four, or even five, a week, or, at an average, in a severe and chronic case, of some two hundred and fifty or three hundred a year.—*Herald of Health*.

SAN FRANCISCO:

Saturday Morning, June 23, 1883.

TABLE OF CONTENTS.

EDITORIALS.—Timbering in Mines—No. 14; Lower California Placers; Booming, 417. Passing Events; New Gold Discoveries; Miners' Accident Relief Societies; Knowledge of Working Miners; Lead, 424. The California College of Mines, 425. Patents and Inventions; Notices of Recent Patents, 428.

ILLUSTRATIONS.—French System of Timbering for Main Levels, 417. View of Berkeley, the University of California and San Francisco Bay, 425.

MECHANICAL PROGRESS.—Hardening and Tempering Steel; Modern Guns and Projectiles; Fast Work in a Carriage Shop; New Adaptation of Electricity; Drilling Glass; Fire Bricks from Flint, 419.

SCIENTIFIC PROGRESS.—Tornadoes; Shall we Smell by Telephone; What Causes the Timber Line; Twinkling during Auroras; Conductivity of Carbon; The Recent Eclipse Observed; Motion of Sun Spots; Movements of Submerged Bodies; Pressure Battery; More Fossil Discoveries at Carson, 419.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends and Bullion Shipments, 420.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon and Utah, 420-1.

USEFUL INFORMATION.—Ancient Mortar; Analysis of the Orange; Protecting Iron from Rust; The Future of the Cottonwood; How to Test Flour; The Glue Pot; Water-Proof Leather; Etching Liquid for Steel; To Protect Brick Walls; Paint for Kitchen Walls, 423.

GOOD HEALTH.—Fireside Chats on "Health; Learning to Swim; The Novel-Reading Disease, 423.

NEWS IN BRIEF.—On page 423 and other pages.
MISCELLANEOUS.—The Constock Lode; The Anti-Miners' Attack Upon the Drill Miners; Carbonate, Colorado; Copper in Arizona, 418. Have Your Claims Patented; The Grain of Wheat, Nevada and Her Merits; Campo Seco Copper Mine; The Violin, 422. Sierra as a Mining County; Queer Ore, 428.

BUSINESS ANNOUNCEMENTS.

Mining Machinery.—Etna Iron Works, S. F.
Assessment Notice.—Gould & Curry M. Co., S. F.
Dividend Notice.—Bulwer Con. M. Co., S. F.

Passing Events.

The breakage of the big mining dam on the Yuba, elsewhere fully alluded to, is a disastrous matter, not only to the company and those directly injured, but to the mining interests. The mines to which it was necessary are our largest gold producers, and of course that source of bullion product is stopped for a time. In a general way it lessens confidence in dams, though that should not be the case, as such accidents are liable to occur to any structure.

The news of a rich mining field in Lower California, full details of which we give in another column, will be read with avidity. Like all rich things, however, there are serious drawbacks.

In the mining regions work is being vigorously prosecuted in all directions, and generally prospects are very favorable for a full yield this year. So many new mines are opened that it is difficult to even keep track of them; yet our "Mining Summary" gives details of all such things.

COPPER IN LIVERPOOL.—Late quotations of copper in Liverpool are: Chile bars, good ordinary brands, £63 10s. to £63 15s. Ore, 12s. 4½d. per unit. The total visible supply is 48,519 tons fine against 51,755 tons on May 1st.

LEAD in Liverpool is selling at £12 17s. 6d. to £13 for English and £12 12s. 6d. per ton for Spanish.

THE deepest mine in Colorado is down 1,400 feet. It is called the California.

New Gold Discoveries.

A Rich Mineral Belt in Faja California, Mexico.

For several years it has been well known that very rich copper mines existed near San Borgia, Baja California. The ore from these mines not only carried from twenty-five to ninety-five per cent of copper, but also from \$8 to \$25 in gold and \$15 to \$250 per ton in silver. There is but very little doubt that the sixty tons of ore bought by the Revere copper works in Boston, twenty-two years ago, and from which white copper was made, equal if not superior to the celebrated "Pang tang" of the Chinese, came from the Morales or San Borgia copper mines. It has also been well known that the richest silver ore ever found in Mexico, was accidentally discovered between San Borgia and Cedros Island shore, by some shipwrecked sailors, and although thirty miles from water, wood or grass, the sailors returned and proved the truth of their reports by showing the ledges or veins, from whence they took there. Within a year a Californian discovered a very rich gold quartz mine, adjoining the San Borgia or Morales copper mines, from which he took \$8,000 in a few days, by pounding the ore or rock in a hand mortar; and his companions or associate miners took their \$5, \$10 and \$20 per day from the same vein. Just how gold, silver and copper, each distinct and separate by itself, could exist within a stone's throw of each other, unmixed, is a mystery unsolved by the practical miner, and a question which may puzzle the geologist and mineralogist to solve. These rich discoveries led to the organizing and sending out last fall, of well equipped prospecting parties, to explore an entirely unknown country. The wet, cold winter was a godsend to them, as water and grass were found everywhere. We are now informed that these parties were at last rewarded by discovering in the last of April, the evidences of gold and finally the gold itself. At first a gulch was found, emptying into the Pacific ocean, twenty miles west of San Borgia, latitude 29°, longitude 114°, about fifteen miles in length, which was rich in placer gold. Nuggets from \$8 to \$360 were found. Men took

\$100 Per Day to the Man.

The gulch was found to have branches of fifteen miles or more in length. The first gold was found on the naked bed rock, made bare by the winter's floods or heavy rains. Upon careful examination it was found that the ancient gravel stream lay about two feet below the surface and that the pay streak, or bed of gravel, was about four feet thick. Subsequent explorations show that the ground or placer belt is seventy-five to 120 miles in length by thirty to forty-five miles in width, with gold in almost every gulch, canyon and ravine.

Difficulties.

No water is found, only for drinking and cooking, and this, in many cases, has to be carried on mules' or burros' backs from 5 to 12 miles, and in one case 20 miles. Twenty miles from the first discoveries there is a large stream of water which can be carried in iron pipes, and used in 20 to 25 miles of the different gulches. As found, this water soon sinks, and is lost in the loose gravel of these desert wastes. Not a stick of fuel is anywhere to be found, only a limited supply of small brush and shrubs, hardly sufficient for cooking. No grass is found, only a few weeds or plants, upon which the small native mule or burro can live. It is impossible for a horse of any kind to live in the entire region.

Distances.

It is 614 miles by land to San Borgia, 594 to the new mines, or where the discoveries were made, from San Diego, Cal., and not less than 400 miles by water from San Diego to Lagoon Heads, or 375 to Rosalia bay. From here to the mines it is about 40 miles over a desert. Small vessels, drawing not over four or five feet of water, can go up the lagoons, Manuella or Black Warrior, for 15 or 20 miles, and within 12 to 20 miles of the new gold fields, over a desert void of water, fuel, or grass. On the east shore of Manuella lagoon, nearest the placers, there used to be fresh water, but nothing is now known whether the well is still there or not. Parties going to the mines should take supplies to last them at least for six months, as not one thing can be had to eat or drink. The heat is intense, 95° to 110° daily in the shade, when there is any, and often 120°, and will continue so for 120 days to come. Water is found in the driest

seasons, from San Diego to San Fernando, every 10 or 15 miles—a distance of 403 miles—and from San Fernando to the new mines every 15 to 25 miles. In the dry season 36 miles is the longest drive to water. Just how rich or how extensive the rich portions of the gold fields will be found, is yet a question which will be solved before January. Hundreds are leaving by land and water for the mines. Parties are returning to different supply points almost daily after provisions, tools, etc., bringing one, two, six and eight pounds of good gold dust with them. This is the best evidence of the gold existing in quantities.

Caution.

Let no one rush off wildly, or without due preparation. If as extensive and rich as reported, there will be enough for all. November or December will be a much better time to go there than at present in the heated season. All the work must be done with dry washers or by fanning out the ground and dirt and leaving the gold. If as reported, the gold fields cannot be worked in six months or in five years, and the working of these placers will develop the vast copper, silver and gold mines near by, the great deposits of nitrate of potash and soda, alum, sulphur and borax, the veins of mica, manganese, spiegel and iron. Let every one wait until the facts are known by those who are already in the mines or on their way there. At least let every one think twice before they start off into such a wild and barren country. Wagons can go from San Diego to San Fernando, a distance of 403 miles over a very fair mountainous road, but no further; only burros or native mules can be used beyond.

Miners' Accident Relief Societies.

In England they now have in the mining districts, excellent institutions known as the "Miners' Fatal Accident Relief Societies," which we might with propriety form in this country. Although the survivors of sufferers by great mining accidents, involving serious loss of life, are often liberally provided for by the munificence of the public, the majority of fatal accidents result in the loss of one or two lives, and in these cases the survivors are almost or entirely neglected—a small contribution of the field club or the owners or other sources, and perhaps the burial expenses usually representing all the assistance received. The only remedy for this is a miners' fatal accident relief society supported by the miners, colliery owners, lessors and the public. Such an association not only provides for the few fatal accidents which awaken public sympathy but also for those numerous cases which do not attract attention, but which are found by experience to entail far more misery than is caused by the great colliery catastrophes. All those who are interested in movements for the relief of the bereaved and destitute will assist a society like this.

The objects of the society are to provide for the widows and children and the payment of legacies to the relatives of unmarried members who may be killed by those casualties which are of such frequent occurrence in and about coal, or other mines or quarries and a sum to defray the funeral expenses of members accidentally killed in and about the pits. This is essentially a workmen's society movement. The men all give it their hearty support. On this coast in the larger camps, some such organization as this could do much good.

ALASKA EDITION.—We shall publish a double edition of the MINING AND SCIENTIFIC PRESS next week devoted mainly to the interests of the Territory of Alaska. We shall give a fine large map of Alaska, showing the mining districts, etc., and other illustrations relating to the region. There will also be considerable information concerning the mines and mining districts, and a good deal of matter of interest to prospectors and miners generally. This special edition will be of value to all who are in search of information about our northern possessions.

The one-ledge theory has been exploded so far as it was supposed to apply to Tomahstone. The *Republican* says that the developments made in that camp tend to prove that there are three distinct formations, in which are boulders, varying in size, are met with, viz., lime, porphyry or quartzite, and the belt known as the manganese formation.

ANTIMONY is selling in England for £39 to £40 per ton for French Star Regulus.

Knowledge of Working Miners.

We have not in this country any of the science classes or colliery institutes such as exist in the mining regions of Great Britain, where the miners who work every day may learn some of the scientific part of mining free of charge if they choose. There they have these things managed so well, that any one desiring may have an opportunity to learn from good instructors, and see experiments carried on which educate him in his calling from day to day. Some of the colliery institutes offer money prizes for essays in mining, restricting the contestants. That is they offer a prize, for instance, to any one not over the grade of an overman. The object is to draw out the intelligence of the working miners and, further, to encourage among them the study of mining and kindred subjects. It encourages the more intelligent miners to compete for the prizes. In a recent notice we see that prizes are offered for "the three best essays on practical mining written by any miner working in or about the coal mines of the South Durham Inspection District."

We have, unfortunately, never made any organized attempt here to assist the practical working miner to learn more than he learns while at his regular work. He does not have much chance to learn the reasons of things except what he picks up from the technical newspapers of the day. And it is to his credit that he has learned a great deal from such sources. Journals like the MINING AND SCIENTIFIC PRESS, which circulate in mining communities, have furnished him with the experiences of others, and with the descriptions of machines, processes and methods, which have enabled him to become more progressive than if he worked away blindly day by day at his labor. None of our rich men who have made their money by mining have ever thought proper to offer prizes for essays on mining from practical men. If this had been done, a great deal of value would no doubt have been added to our literature on the subject.

These men who blast and pick, and timber, and do other work under ground have experiences which, if properly formulated and presented to the world, would be of the greatest utility in future work. They study Nature in their own way, but generally without the aid of scientific training, which is reserved for the few. Nevertheless, were it possible to obtain from them various experiences, the world would be the gainer. Every district has its peculiarities, learned only by the men who wield the miners' tools.

Lead.

California is not now much of a lead producer, but Nevada continues to produce large quantities. Utah is the heaviest producer, shipping large amounts East, and now working some of it up into sheet and pipe, and making white lead. A good deal of argentiferous galena has been mined in Castle Dome district, Arizona, and smelted at the Selby Lead Works, in this city. As this ore ran low in silver, its extraction may be said to have come the nearest to anything that has been done in the way of lead mining proper, the value of most of the plumbiferous ores treated here consisting of gold and silver. We have not worked any ores of this class exclusively for the lead they contained. For a long time 5,000 or 6,000 tons of lead were exported from this city to China, where it is used largely as lining for tea chests; but the Chinese now get most of their supplies from England.

For the past ten or twelve years the Selby Lead Co. have turned out an average of 6,000 tons of lead. About 3,000 tons of this they now manufacture into bars, shot, pipe, sheet lead, etc., in which shape it is consumed on this coast.

The Richmond Con. Co., at Eureka, Nev., has for a very long time been turning out about 4,500 tons a year. The Eureka Con. produces about the same amount, which is sent as crude bullion to the Selby Smelting Works here. During 1877 and 1878 the price of lead was low, and the production was checked on this coast. The industry is now fairly prosperous, and promises to expand under present conditions. The Wood River country, Idaho, produced about 4,000 tons of lead in 1881, and 5,000 in 1882. Most of that made in 1881 was from ore shipped to Salt Lake and Omaha. Last year one-third as much was produced by smelters in the county. It is thought these Wood River mines will produce 6,500 tons this year.

The California College of Mines.

The University of California is an institution wisely planned and richly equipped, and its faculty includes scholars most eminent in the country in their special lines of thought and investigation. The institution, too, is most delightfully and eligibly situated. Its fame is being widely spread, and its future expansion and growth will be commensurate with the progress of our better half of the country.

Our engraving shows the University buildings and grounds, the surrounding town of Berkeley, the beautiful bay of San Francisco, and beyond are the Golden Gate and the city of San Francisco. Seen from San Francisco, Berkeley seems a gray, ribbon-like strip, drawn close in between the water and the hills. More closely observed, it expands into a broad slope, or tilted plane, with a rise so gradual that, in crossing it, one attains a considerable elevation before he is aware that he has left the level of the ocean. Hence, it has hight without the effort of ascent, and those desirable accidents of light, pure air, and an ample prospect, which includes plain, valley, mountain, inlet, island, and nearly every other incidental feature of earth, water and atmosphere, considered essential to fine landscape. This natural panorama

University by D. O. Mills, Esq.; the Pioche collection, an extensive miscellaneous collection of minerals, rocks, ores, shells, etc., from all parts of the world, and especially from South America, presented to the University by the late F. L. A. Pioche; the Hanks collection, consisting of miscellaneous minerals and rocks, presented by James R. Keene, Esq., of San Francisco; selections from the Ward series of casts, purchased by the University; and current donations.

The Museum of Historical Geology is in process of formation. The Museum of Paleontology contains a full suite of the fossils of California, both animal and vegetable. Most of these have been already described and figured; the animals in the State Geological reports of Professor J. D. Whitney, and the plants, by M. Lesquereux, in the Memoirs of the Museum of Comparative Anatomy of Harvard. The paleontological material from the Voy collection has, however, never been worked up, and offers, consequently, to the student an excellent field for original work. There are also selections from the series of Ward casts.

The Museum of Petrography contains many foreign rocks, but is especially rich in California material, collected by the corps of the State Geological Survey and by Mr. C. D. Voy. The rocks are being arranged systematically and geographically, so that, as the collection be-

for investigation, facilities for which are freely placed at the disposal of the student. All of the foregoing museums are open at all times to the public, Mr. Rivers being in constant attendance to show visitors through the various collections.

Chemical, Assaying, and Metallurgical Laboratories.

The chemical laboratories are planned after the most careful study of the newest and best arranged laboratories of this country and of Europe, with the aid and advice of many experienced teachers of analytical chemistry. There are two principal laboratory rooms, one for qualitative analysis, the other for quantitative analysis, each having accommodations for thirty-two pupils. They contain a number of evaporating niches, sand and steam baths, drying ovens, filter apparatus, etc. There are rooms all well equipped for fusions, organic analysis, gas analysis, etc.; also a balance room, with balances from the best makers. Such apparatus as is needed for the study of analytical chemistry is loaned to the students, without charge. There is a good supply of apparatus for carrying on original investigation.

The metallurgical laboratories are large and well equipped. The assaying laboratory is designed to offer every facility for the assays of all kinds of ores, bullion, slags, mattes, etc. The crushing and sampling room contains large

tery, amalgamating pans, settlers, concentrating apparatus, roasting furnace and leaching apparatus, and will enable students who have finished the undergraduate course in metallurgy and assaying, to sample, assay and then treat by the methods in actual use, most of the gold and silver ores of California. In all such cases, the student will be required to determine amount and causes of losses, and the expense of treatment.

Mineralogical and Petrographical Laboratories.

The mineralogical laboratory is provided with a large collection of unlabeled minerals, which students determine by their physical properties. A separate course on blowpipe is offered by the chemical department. Special students on mineralogy will find every facility for investigations in optical mineralogy. The apparatus at disposal consists of a large reflection goniometer and spectrometer (reading direct to ten seconds), from Fuess, in Berlin; also, from the same maker, Groth's Universal Apparatus, consisting of a polarization instrument for both parallel and converging polarized light, an apparatus for determining the angle of optical axes, and a small goniometer and spectrometer; also, an apparatus for cutting and grinding crystal sections.

In the petrographical laboratory every facility is furnished for the study of rocks, both by the ordinary process of mineralogical investigation

VIEW OF BERKELEY, THE UNIVERSITY OF CALIFORNIA AND SAN FRANCISCO BAY.

of San Francisco bay and the adjacent hills is especially remarkable for a refined variety of outline and color, but the noblest effects are not wanting.

In preparing the view which we present, the artist stood upon one of the low hills in rear of the University grounds, and the reader looks with him down upon the campus, with its trees, shrubbery and openings, upon the rear side of the buildings, and thence westward upon the slope of the Berkeley plain and the bay beyond. Of the four large buildings shown, that upon the left is the College of Agriculture. The building semi-circular in form is the Bacon Art and Library building. Next to the right is the College of Letters. The last of the four buildings, partly hidden among the trees, is the College of Mining and Mechanical Arts, of brick, four stories high. It is devoted to the studies implied by its name, and is splendidly fitted out for its uses. Some description of this department will interest our mining readers.

The Collections of the University.

In the first place, to the mining student, great interest centers in the geological, mineralogical and paleontological collections of the University. The collections are made up from materials obtained mainly from the following sources: The State Geological collection, which has been placed at the disposal of the University; the Voy collection, consisting of a large number of California fossils, minerals, rocks, etc., collected by Mr. C. D. Voy, and presented to the

comes more complete, the geographical distribution of the rocks of the Pacific coast will be known with great accuracy and detail. It is designed to issue, as soon as possible, a descriptive catalogue of the rocks of California.

The Museum of Economic Geology, although so recently founded, is already large, and is in frequent receipt of valuable acquisitions from all parts of the Pacific coast. The importance and value of this collection can scarcely be overestimated. It will subserve two purposes—on the one hand it renders possible a course of instruction in ore deposits, which is of essential importance to those who intend to pursue the profession of mining engineer, and, on the other hand, the ore deposits of this coast will be collected together for the first time in one institution, where they can be subjected to careful and critical comparative investigation, to the end that the laws of their occurrence may, as far as possible, be determined. To this end an elaborate blank book has been devised, in which are carefully tabulated the name, locality, form, thickness, dip, strike, wall rocks, etc., of every ore deposit on the coast, as soon as accurate information upon these points can be obtained. The mass of statistics thus obtained will be made the basis of the above-mentioned investigations.

The Museum of Mineralogy is very large and fully arranged, and is supplied with ample case room. It fully illustrates the instruction in mineralogy, and offers inexhaustible material

iron mortars and rubbers (a panning sink), an assortment of sieves, and a large sampling table. Another room is devoted to the ore or pulp scales and the fluxes, and contains a hood with burners and stands for parting gold and silver. The furnace room contains four crucible furnaces and three muffle furnaces, arranged for burning coke, a large Freiberg muffle furnace, and one for crucibles arranged to burn soft coal. These furnaces have all been carefully designed and are built into the walls and ironclad in a substantial manner. A storeroom and a weighing room for the assay balances complete the lower floor. On the floor above, a large room, devoted to bullion and volumetric assays, contains a pair of muffle furnaces, parting hoods, a galvanic battery, work benches, tools and a pair of steel rolls. Another room, lighted by yellow-glass windows, is devoted to the humid or mint assays. A third room, for special investigations, contains a gas muffle furnace and one for crucible assays; also a water-blast blowpipe and a distillation apparatus. A special balance room is arranged on this floor for the finest assay balances. All the appliances are of the most improved pattern, and offer excellent opportunities for instruction and original research. The only charges are for the materials actually used by the students.

The appropriation lately made by the Legislature for this college will be at once applied to the construction of a metallurgical laboratory. It will contain a small rock breaker, stamp bat-

and by the preparation of thin rock sections and an examination under the microscope. The laboratory possesses six first class microscopes. The student has access at all times to the facilities provided for this work, and the material to be investigated is practically inexhaustible.

The Mining Course.

The Course in Mining is designed for students who wish to become mining or metallurgical engineers, or to engage in one of the many pursuits connected with the mining industries, such as the surveying and mapping of mines, the assaying and working of ores, the designing and use of mining machinery, or the exploitation of mines. In order that people in the mining regions may know what may be learned in the course, the following is presented:

The undergraduate course includes a thorough preparation in the modern physical sciences, training in English, and the acquisition of a reading power of German (or French). It may be completed by the average student in four years. Instruction is given according to the nature of the subject, either by lectures and recitations, or by practical exercises. The lectures are fully illustrated. The practical exercises consist of laboratory and field work, in which each student does the work himself under proper guidance. The following is an outline of the course in addition to English and German (or French):

(Formerly Huhn & Luckhardt.)
Mining Engineers and Metallurgists

JOHN TAYLOR & CO.,

IMPORTERS OF AND DEALERS IN

Assayers' Materials, MINE and MILL SUPPLIES,

CHEMICAL APPARATUS AND CHEMICALS, DRUG
GISTS' GLASSWARE AND SUNDRIES, Etc.

118 and 120 Market Street, and 15 and 17
California St., San Francisco.

We would call the attention of Assayers, Chemists,
Mining Companies, Milling Companies, Prospectors, etc.,
to our full stock of Balances, Furnaces, Muffles, Crucibles,
Scorifiers, etc., including, also, a full stock of
Chemicals.

Having been engaged in furnishing these supplies since
the first discovery of mines on the Pacific Coast, we feel
confident from our experience we can well suit the de-
mand for these goods both as to quality and price. Our
New Illustrated Catalogue, with prices, will be sent on
application.

Our Gold and Silver Tables, showing the value per
ounce Troy at different degrees of fineness, and valuable
tables for computation of assays in grains and grammes,
will be sent free upon application. Agents for the Patent
Plumbago Crucible Co., London, England.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American
Machine and Model Works, 111 and 113 First St., a
Rutherford Pulverizer, an improved revolving barrel
crusher, which was only used a few times and is as good
as new. It will be sold very much below cost, and
miners who are in need of such an appliance for a small
mine will do well to make inquiries concerning it. It is
suitable for a pulverizing mill for powder or other sub-
stances. Reference as to above can be had upon applying
to this office.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Buffon and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. R. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Holists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. **HAULDIE IMPROVED ORE TRAMWAYS.** We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x30. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St

CONTINENTAL WORKS, BROOKLYN, N. Y.

Duc's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL, OILITE, MANGANESE, IRON ORES,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 20 H. P. For circulars and full particulars apply to or address,

MILL & MINING MACHINERY.

F. A. HUNTINGTON,

No. 45 Fremont Street.

San Francisco, Cal.

PATTEN'S

CONCENTRATOR

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation. The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp batter.

F. A. HUNTINGTON'S

CAPACITY AND DURABILITY GUARANTEED.

MILLS ERRECTED WITH ALL APPLIANCES COMPLETE.

CENTRIFUGAL ROLLER QUARTZ MILL!

After running one of these mills on the Whidden mine, in El Dorado county, over four months, and thoroughly testing its capacity and durability, I am prepared to offer it to the mining public, and claim for it the following advantages over the drop stamp mill:

1. The cost of same capacity is not more than one-half that of stamps.
2. Freight to mine one-fourth that of stamps.
3. Cost of erection at mine one-tenth that of stamps.
4. It runs with one-third the power per ton of ore crushed.
5. The wear is less than that of stamps.
6. The wearing parts are easily duplicated.
7. It has a much better discharge, and leaves the pulp in better condition for concentrating.
8. It is a better Amalgamator, saving fully nine-tenths of the gold in the mill; the balance can be saved on plates in the usual manner.
9. It is continually crushing; not like the stamp, using power to suspend it in air ninety-nine one-hundredths of the time, and the balances making a thundering noise, and accomplishing comparatively small results. It is as far in advance of the stamp mill as the present method of making flour with improved rolls is over the Indian's mode of crushing corn in a stone mortar.

F. A. HUNTINGTON, ESQ.—DEAR SIR: Your centrifugal Roller Quartz Mill has run on the Whidden Gold Mining Company's property, at Shingle Spring, El Dorado county, Cal., about four months, and it did good and satisfactory work; a greater portion of gold remaining in the mill than in a stamp battery.

FRED. JONES, Supt.

SHINGLE MACHINES AND SAWMILL MACHINERY OF EVERY DESCRIPTION.

279,438. SADDLE HORN.—O. Ruparts, Albany, Oregon.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

AUTOMATIC RAILWAY ALARM.—Frank Clifford, Carson City, Nev. No. 279,225. Dated June 12, 1883. This invention relates to a novel automatic railway alarm to be used at crossings; and it consists in a mechanism attached to the locomotive, preferably between the cylinder and the first driver, consisting of a revolving hub, provided with peculiar forked arms, which, by coming in contact with posts placed suitably upon the side of the track, are turned to revolve a disk, furnished with an eccentric groove, in which a stud upon the end of a piston, connected through intermediate devices with the steam-whistle travels. There is a peculiar hand connection to operate the whistle. The object of this invention is to prevent accidents at points where roads cross the railway track and this is done by sounding an alarm, which, by reason of the operating mechanism, is not dependent upon vigilance of the engineer, but is automatic in its operation.

TWO-WHEELED VEHICLE.—Nelson Peterson, Antioch. No. 279,428. Dated June 12, 1883. This invention relates to the class of two-wheeled vehicles known as "carts," and to certain improvements therein. The invention consists in a hinge connection in the main body supporting springs and the axle, and in combination therewith of suitable connections between the ends of the springs and the shafts of their cross-bars. The object of the invention is to overcome as much as possible the joggling motion of the horse, which is usually communicated to the seat, and the object is attained by such a construction as to break the rigid connection between the shafts and axle and the remaining parts of the vehicle.

SUSPENSION HOOK.—Samuel J. Fletcher, San Francisco. No. 279,236. Dated June 12, 1883. This invention relates to a new and useful suspension hook for sustaining curtains, drapery, etc., and it consists in a double plate, having a swivel hook in its top, and in a screw-eye passing through said plate and receiving a nut. A particular adaptation of this hook is to suspend from it at the same time the heavier curtains or drapery and also the lace curtains to the best advantage. The usual way in which curtains are suspended is by a cornice, or a horizontal pole upon which are fitted a number of rings. These rings have eyes or staples in them, and some kind of hooks or pins are secured to the curtain and engage with the screw-eyes to suspend them. All these hooks have in some way to be sewed to or pinned into the material, and they cannot be made ornamental, nor can they be applied with much readiness. The lace curtains are secured to a rod behind the pole, and are drawn up so tight that they are seen from the inside above the droop of the heavier curtains. It is the object of this invention to provide a hook adapted to be readily applied, capable of ornamentation, and which will suspend from itself both the heavier curtains and the lace curtains.

TELEMETRY.—Win. D. Patterson, S. F. No. 279,273. Dated June 12, 1883. This invention relates to a new and useful telemetry, and consists in a tube having a means at one end for observing the direct and reflected rays of light from the object, and a means at the other end for causing the reflected ray to coincide with the direct ray, and for reading the angle of the reflected ray, whereby said angle, the base and the right angle of the direct ray with the line of collimation in the tube being known, the size of the angle of the reflected ray may be readily computed and the distance of the object

ascertained. The object of this invention is to ascertain the linear distance to any given object, and to provide for this purpose a simple and effective instrument.

ORCHARD CULTIVATOR.—Gains Richardson and Geo. Enderson, San Jose. No. 279,277. Dated June 12, 1883. This invention relates to a new and useful cultivator, especially designed for use around trees in orchards, etc. The invention consists in a frame, the teeth of which on one side of the center are set in an opposite direction to those upon the other side. The center of the frame is provided with a bearing for embracing the trunk of the tree, and a means for rendering it adjustable to fit different sizes of trees.

VEHICLE SEAT.—Jos. Newman, Sacramento. No. 279,266. Dated June 12th, 1883. This invention relates to a new and useful improvement in vehicle seats, and it consists in a cushion socket or recess, in connection with the shell, and in the construction, whereby this socket is formed. The seats of vehicles are usually constructed with a bottom portion to sustain the cushion and flaring portion, called technically the "shell," to confine the cushion, and to form a slight back or rest for the occupant. This shell is built right out from the bottom, and is generally not more than six inches high. The cushion is then laid on the seat. In certain classes of vehicles, notably in those known as "side cars," the springs are made rather light for sake of the appearance, and therefore they do not ride as easily as others. In order to compensate for this, cushions have been used which have been somewhat of an improvement, and this demonstrates that greater improvement can be made in this direction, if it were possible to use cushions having deeper springs. In the present construction of the seat this is not possible, and the cushion, being thicker, would throw the rider uncomfortably high; or by lowering or dropping the bottom of the seat, forming a socket, or recess, below the shell, a thick cushion having deep springs may be used, and the result attained. This is the object of this invention, namely, to be enabled to use a cushion having deep springs without throwing the rider too high.

News in Brief.

A HALIBUT, weighing 202 pounds, has been caught in Puget sound, near Whatcom, W. T.

THERE is more than \$2,000,000 worth of opium in the Appraiser's store in San Francisco.

The Suez company has agreed with the English Government as to the terms of making the second canal.

So crowded are the hotels at Seattle, W. T., that many people are unable to find sleeping accommodations.

The Salvation Army now, it is stated, numbers 484 corps, with 1,500,000 members, whilst the income amounts to £121,000.

THE exports of wheat from the port of New York from June 1st to June 20th will be about 145,000,000 bushels, against 132,000,000 last year.

DE LESSER estimates that the cutting to flood the North African desert can be completed in five years, at a cost of not more than \$30,000,000.

LOVE is much elated at the result of the trial of J. W. Saunders, one of the leaders in the riot when a saloon was destroyed in that town some months ago.

THERE were about seven hundred and fifty wheelmen in line at the third annual meet of American wheelmen, held in New York, May 28th, and the procession was one mile in length.

It is stated that at Red Rock canyon, on the regular road from Mojave to Independence, the carcasses of 2,000 sheep are lying, polluting the atmosphere for miles about. It is surmised that they were poisoned by the bad water of that place.

Etna Iron Works.

Attention is called to the advertisement of the firm of Starr, Malter & Co., of Nos. 217, 219 and 221 Fremont street, San Francisco, who have thoroughly reorganized the business formerly conducted by Messrs. Pendegast, Smith & Co., well known as the Etna Iron Works. The affairs of the old firm were satisfactorily adjusted in the interest of former creditors, whose accounts were liquidated almost entirely in full, the honor of which action being due to Messrs. Malter & Starr, who came promptly forward, voluntarily meeting the creditors in an honorable, upright manner, thereby saving the reputation of the old concern, and also adding to their own. As heretofore the business will be manufacturing general iron work, marine, steam and hydraulic engines, but they will make a specialty of mining machinery. New improvements in machinery and apparatus of all modern kinds have been added in the various departments, making these works very complete in all detail. A new office of general superintendent has been created, and good choice was demonstrated in selecting the former superintendent, Mr. Geo. Birrell, to fill the place. He is a young man thoroughly practical in every department of manufacturing, having learned and graduated in the business in this city. He is eminently fitted to bold so important a trust, and under his supervision the Etna Iron Works should not fail of success.

The California College of Mines.

(CONTINUED FROM PAGE 425.)

Mathematics.—Algebra, geometry, trigonometry, analytical and descriptive geometry, differential and integral calculus.

Physics.—A course of lectures on experimental physics: heat, light, sound and electricity, followed by practice in the physical laboratory.

Chemistry.—Experimental lectures and recitations on inorganic chemistry, particular attention being paid to the chemistry of the metals as a basis for subsequent work in metallurgy. Also, extensive laboratory practice in the qualitative and quantitative analysis of minerals, ores, rocks, and metallurgical products. The use of the blowpipe is taught in connection with this work. Quantitative analysis is elective with surveying, but is required of those who intend to become candidates for the degree of Metallurgical Engineer.

Mineralogy.—Lectures on crystallography and the physical properties and uses of the most important ore, gangue and rock-forming minerals. The course is illustrated by numerous models and a collection of over 10,000 minerals. Considerable time is devoted to practice in the determination of minerals by the use of the knife, lens and streak-plate. The working collection for this purpose alone contains over 2,000 specimens.

Geology.—A course of lectures on dynamical, structural and historical geology. The course is illustrated by numerous drawings, casts and models of fossils.

Mechanics.—Lectures on analytic mechanics; strength of material with applications to framing, timbering and machine construction; hydraulics, pressure of water in dams and reservoirs, flow of water in pipes and ditches, hydraulic motors. The course is illustrated by numerous problems and applications.

Mechanical Drawing and Construction.—These are made, as far as possible, an application of the course in mechanics to mining and metallurgical engineering. Instruction is given in designing machinery and fixed structures for mining and metallurgical work.

Surveying.—This course includes: Land and topographical surveying and leveling; the laying out of roads, tramways, ditches, pipe lines, mining claims; underground work; extensive practice in the field with compass, transit, level and plane table, and the plotting of field notes and construction of maps and sections. The instruments and grounds of the University furnish excellent facilities for this work. The course in surveying is elective with quantitative analysis, but is required for those who intend to become candidates for the degree of Mining Engineer.

Mining.—Nature and mode of occurrence of ores; prospecting and exploring ore deposits; United States laws governing location of claims; open cut and quarry work; hand and machine drilling; explosives; blasting; tunneling, with methods of excavation and timbering; shaft sinking, timbering and walling; stoping; tramming; hoisting; pumping and drainage; lighting; hydraulic mining; general organization and administration. The course is illustrated by drawings, sketches, data, and references to typical mines in operation on the coast.

Metallurgy.—(General part): Classification of ores and processes; crushing and sampling ores; fuels; fluxes; refractory materials; furnaces; accessory machinery; metallurgical products. (Special part): The metals selected are the ones at present most important on this coast—gold, silver, lead and quicksilver. Both wet and dry methods of reduction are taken up and discussed in detail. The illustrations and data are drawn, as far as possible, from actual work on the coast.

Assaying.—The fire assays accompany each metal in the course of metallurgy, and the instruction is made, as far as possible, to illustrate the methods of reduction used on the large scale. Particular attention is paid to the fire assays of ores of gold, silver, lead and quicksilver. The assays of fuels and the remaining useful metals are elective with advanced work in construction.

Thesis.—The undergraduate course concludes with the preparation of an original thesis on some subject connected with mining or metallurgy.

Excursions.—Students are urged to use their holidays and shorter vacations throughout the course to visit and study the many large machine shops, foundries, rolling mills, powder, smelting and other technical works in the vicinity of Berkeley, Oakland and San Francisco. They are also urged to use their summer vacation of two months, and their winter vacation of three weeks, to visit and study various typical mines and reduction works at a greater distance. Students who earnestly and systematically pursue the above plan not only do better and more intelligent work at college, but make acquaintances and acquire a fund of information that is afterwards of great practical use to them.

Postgraduate Courses.

Students desiring any time to pursue advanced or special work after graduation, will find every facility extended to them which the libraries, laboratories and collections of the University offer.

Candidates for professional degrees in this college must satisfy the following conditions:

A candidate for the degree of Mining Engineer must be a graduate of the College of Min-

ing of the University, or he must give evidence satisfactory to the Faculty of having successfully pursued a course of study, equivalent to that given in the College of Mining in the University.

In addition to this he must pass a satisfactory examination in the following subjects: mining, ore dressing, petrography, economic geology, thermodynamics (elements), drawing and construction of mining machinery, blowpipe assaying, and political economy. He must have had at least one year of actual practice in the field, in the course chosen, and must show by an original memoir upon some subject bearing upon this profession, his power to apply his knowledge to practice. This degree will not be given earlier than three years after graduation.

A candidate for the degree of Metallurgical Engineer must pass an examination in the following subjects: Metallurgy, ore dressing, assaying and analysis, blowpipe assaying, thermodynamics (elements), drawing and construction of furnaces and metallurgical machinery and political economy. In all other respects the requirements are similar to those stated for the degree of Mining Engineer.

Special and Partial Course Students.—Students who may not be able to take the full undergraduate course may attend such classes in mining, metallurgy or assaying as they may be prepared to enter.

Petrography and Economic Geology.

In the chemical course the instruction is petrography, covers the following ground: (1) The different methods of rock investigation, viz., physical and chemical; (2) rock texture and rock structure; (3) the different forms in which rock masses occur; (4) classification and nomenclature of the leading systems proposed; (5) descriptive petrography, special attention being given to the rocks of California; (6) petrogenesis, or the origin of rocks; (7) changes and decompositions which rocks undergo. The laboratory is well equipped, and the student has every opportunity for practice in the determination of minerals by the microscope and ordinary mineralogical methods. A large field for original research is open to the student in the museum of petrography. The course is open to all students who have completed the University course in mineralogy, or an equivalent course elsewhere.

The course of instruction in economic geology consists (1) of a consideration of the geological nature of ore deposits; (2) a special description of the ore deposits of this country, with references to the most instructive examples of foreign ore deposits. The course is illustrated by geological maps and charts, and sets of specimens of ores and wall rocks from the principal ore deposits on this coast.

PACIFIC MILL COMPANY.—Following is the list of officers of the Pacific Mill and Mining Co.: Trustees—W. S. Lyle, J. W. Mackay, George Congdon, C. O'Connor and George Frier. President, J. W. Mackay; Vice-President, George Congdon; Superintendent, D. B. Lyman; Secretary, W. H. Lowell.

A TRUE strengthening medicine and health renewer is Brown's Iron Bitters.

CAPTAIN WEBB, champion swimmer, will undertake to swim through the Niagara whirlpool on the 21st of July. The \$10,000 subscribed is raised by railway companies, who are using it as a grand advertisement, and will run special excursion trains.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times,) by turning a leaf.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

- G. W. McGREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JARED C. HOAG—California.
B. W. CROWELL—Arizona Territory.
N. H. HARGOOD—Plumas county.
M. H. JOHNS—Eureka, Nev.

F. W. STRATTON—Sierra and Yuba counties.
J. J. BARTLELL—Yolo county.
JAMES W. BOYER—Sacramento county.

DON'T FORGET THE STAMP.—Always take a last look at a letter before posting to see that the stamp is in place. Recently one of our agents in Los Angeles county found a letter containing \$3 for one year's subscription to our paper, held for postage which the writer no doubt thought he had duly stamped, and but for the incidental finding of it by our agent, would of course have supposed we had received the money at the proper time. Let all subscribers when remitting or ordering their paper stopped be sure they duly stamp their letters.

CORRESPONDENCE is cordially solicited from reliable sources upon all topics of interest and value to our readers.

ADDRESS all correspondence to the name of the paper, or firm, as either of the publishers or editors connected with the office are quite likely to be absent at times.

Recent Contributions to the California
State Mining Bureau.[Furnished for publication in the MINING AND SCIENTIFIC
PRESS by HENRY G. HANKS, State Mineralogist.]

5012. Large Specimen containing Fossil Oysters Posa creek, foothills of Sierra Nevada, Kern county, Cal. K. Donnelly, M. D.

LOTS OF WORK FOR THE CARSON MINT.—An attache of the branch mint at Carson informs the Reno Gazette that the authorities at Washington do not buy any bullion for it, but let it stand on its own bottom. They fix the price it can pay for silver and allow any one party the privilege of depositing as high as 10,000 ounces a day. If people bring sufficient metal there to keep it running, well and good; if not it shuts down. Just now quite a lot of bullion is being put in every day, and it is piling up much faster than it can be coined. There is several months' supply on hand now, and there is no reason why the inflow should cease so long as Southern Nevada and the Comstock yield anything.

AN EXPERIMENT.—Thirty tons of sulphurets from the Murebie mine have been shipped to Omaha to be worked by a new process, which, it is claimed, returns a larger per cent of the precious metal than any of the processes in use on this coast. It is an experiment on the part of the Murebie mining company, and the result will be awaited with interest by the other mining companies hereabouts. The sulphurets are valued at \$250 per ton.—*Nevada City Herald.*

ELECTRICAL BALLOON.—Tissandier, the French balloonist, proposes to build a balloon to be driven by an electro-dynamic machine fed by accumulators. The balloon is to be elliptic in shape, and about 40 meters long. It is calculated to have a total lifting power of 7,000 lbs., or, after deducting the weight of the accumulators, a capacity of raising fully 2,000 lbs. of freight and passengers.

If you are sick and troubled with dyspepsia, Brown's Iron Bitters will cure you.

Attend to This.

Our subscribers will find the date they have paid to printed on the label of their paper. If it is not correct, or if the paper should ever come beyond the time desired, be sure to notify the publishers by letter or postal card. If we are not notified within a reasonable time, we cannot be responsible for the errors or omission of agents.

ORE PULVERIZER.—The rotary ore pulverizer, advertised in another column as for sale by Mr. Heald, has been used but very slightly, and is a bargain to any one in want of such a machine. It is only sold because the company which ordered it is dissolved, and there is no possible use for it. All the necessary gearing, frame, etc., go with the pulverizer, which can be set running in half an hour after it is received. Parties needing something which will grind ore fine, will do well to communicate with Mr. Heald concerning this machine.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

THE OVERLAND MONTHLY,

A Monthly Magazine.

Devoted to the best interest of the Pacific Coast. This magazine is the exponent of a vigorous literature and has what is so hard to create, A DISTINCTIVE FLAVOR.

N. B.—Mr. J. L. Boone has been connected with the Patent business for over 15 years, and devotes himself almost exclusively to Patent litigation and kindred branches.

No Whiskey!

BROWN'S IRON BITTERS is one of the very few tonic medicines that are not composed mostly of alcohol or whiskey, thus becoming a fruitful source of intemperance by promoting a desire for rum.

BROWN'S IRON BITTERS is guaranteed to be a non-intoxicating stimulant, and it will, in nearly every case, take the place of all liquor, and at the same time absolutely kill the desire for whiskey and other intoxicating beverages.

Rev. G. W. RICE, editor of the *American Christian Review*, says of Brown's Iron Bitters:

Cin., O., Nov. 16, 1881.

Gents:—The foolish wasting of vital force in business, pleasure, and vicious indulgence of our people, makes your preparation a necessity; and if applied, will save hundreds who resort to saloons for temporary recuperation.

BROWN'S IRON BITTERS has been thoroughly tested for dyspepsia, indigestion, biliousness, weakness, debility, overwork, rheumatism, neuralgia, consumption, liver complaints, kidney troubles, &c., and it never fails to render speedy and permanent relief.

Is the Best Pump in the World. Another New Improvement is Lewis' Patent Spray Attachment.

Can change from solid stream to spray instantly. Regular retail price, \$6. Weight, 4 lbs. Length, 32 inches.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

EXCELSIOR BLASTING POWDER,

Manufactured by the

EXCELSIOR POWDER COMPANY.

This is no new, patent, non-explosive Safety Powder, but the Genuine Standard Nitro-Glycerine Powder, as safe to use and handle as any other Nitro-Glycerine Powder manufactured. The fumes and gases, common in nitro-glycerine powders, are destroyed, and do not leave the miner with headache or nausea.

The powder is put up in cartridges of any size to suit the consumer, and is exploded in the same manner as all other high explosives; that is, by means of cap and fuse, or by electricity. It is not claimed for this powder that it is a non-explosive, or safer than other nitro-glycerine powder. All powder, and especially nitro-glycerine powder, should be handled carefully. The EXCELSIOR POWDER is as safe, and for strength far surpasses any other powder on the market. Address all orders to

SEND FOR CIRCULAR.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR, —OR— VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make users of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 22, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

Galvanic Treatment of Copper and Silver Ores.

Experiments are being made in Japan with a view to the introduction of the use of the galvanic process of treating silver ores. The solution of chloride of silver in salt (chloride of sodium), obtained by the Augustin process, has been treated thus. A great difficulty experienced has been to find a proper material for the electrodes. Platinum is excellent, but costs too much, with a bath 100 centimetres deep, and with a sectional area of 100 centimetres of the copper conductors, the requisite amount of platinum being at least 70 kilogrammes. Gold, silver, quicksilver and all base metals being dissolved by the chlorine, set free by the decomposition of the chloride of silver, cannot be used. Advantage has been taken of this dissolving power of the chlorine, set free after many trials, in the following way, but only on a small scale thus far.

Two Becker glasses, A and B, are partly filled with a salt solution of chloride of silver, and connected by the tube, C, whose ends are bound with linen cloth to prevent the entrance of any solid substances. Two electrodes of platinum wire are introduced into the glasses as shown in the figure, the cathode in A and the anode in B.

The decomposition of the dissolved chloride commences and the chlorine set free attacks the copper (for instance) pyrites. There are formed HCl Cu Cl_2 Fe Cl_3 , and also Cu SO_4 and Fe SO_4 , these last sulphates being changed by the chloride of sodium, so long as this is present, to Cu Cl_2 Fe Cl_3 and sulphate of soda (Na_2 SO_4). The necessary supply of chloride of sodium (which is constantly being decomposed) is effected by allowing fresh salt solution to drop constantly from a vessel D. Thus there is maintained a flow of the solution through C to A, when the excess, holding principally sulphate of soda, is drawn off by a syphon as shown.

The chlorides which go into solution are being constantly decomposed—copper, iron, silver, etc., are precipitated on the bottom of A, in slightly coherent masses, while the chloride attacks anew fresh bodies of ore. The process continues without interruption until all the ore is decomposed and all the metal precipitated.

The process has been used successfully only in the laboratory, but trials are being made with a view to its introduction on a large scale. Where power is cheap it promises to be valuable, especially for ore rich in lime, which has been very difficult to treat successfully by other methods.—*B. u. H. Zeitung.*

Mining Expedition to Alaska.

An expedition left here last week in a schooner with a party of miners who are going to work certain mines in Alaska for parties in Oakland. They go well equipped in every respect, though starting rather late. Col. A. F. Williams, of Oakland, was in Alaska some ten years since and located an argentiferous galena mine near Golovin bay, Norton sound. We had a conversation last week with Col. Williams, and also the captain of the expedition. They expressed themselves confident of developing a fine property. The ore is almost pure galena, and runs up over \$150 per ton in silver.

The country all about the region visited by Col. Williams and party is a very difficult one

to prospect in, but this is not on account of the heavy timber, as most people suppose. This heavy timber is more prevalent in the southern part of the Territory. But there is a heavy coat of moss covering the whole face of the country, making it very hard to get about. In fact, it is a most villainous country to get about in. The moss is from one to two feet thick, and the ground is more or less boggy, so that if one

BECKER GLASSES FOR TREATING SILVER AND COPPER ORES.

steps off the moss bed, he is apt to get into the bog. Ten or twelve miles is a good day's travel, so it is very hard to prospect.

There are belts of timber here and there, but the mountains are generally barren and free from brush and trees. Yet there is timber here and there, and plenty for fuel or mining purposes.

The country rock is mainly a micaceous slate;

WORKING BEACH DIGGINGS IN NEW ZEALAND.

but no gold was found. The mountains seem to be of a white spar, which some suppose to be lime. There are great dikes of granite extending for miles and miles. No sulphurets of iron were found anywhere. There is plenty of mica in great scales and sheets.

At a meeting of British shipowners in London, on June 28th, opinions were received from eminent English counsel which were decidedly against the monopoly of Count de Lesseps of the work of construction of the new canal across the Isthmus of Suez. A committee of shipowners will forthwith demand power to construct the canal.

The Outlook.

Mr. Evarts, in his Centennial oration in Philadelphia, made this remark: "All the modifications of European politics accept the popular principles of our system and extend to our model. The movement towards equality of representation, with the enlargement of suffrage and public education in England, the

that it was inevitable, and the sooner kings and potentates made up their mind to meet it the better for them. Everywhere are indications that the empire of one ruler is over, that the reign of the million has begun. The person of every monarch is hedged about with bayonets. The bomb that burst under the coach of the Czar of Russia in the streets of Petersburg shook every throne in Europe. Everybody has heard of Bortholdi's statue of "Liberty Enlightening the World," now nearly completed by the French sculptor. It is to be presented by the Republic of France to the Republic of America, and placed in the harbor of New York. It is 150 feet in length, and will stand on a pedestal of equal height. One arm of the magnificent figure supports an uplifted torch which will be a brilliant electric light at an elevation of more than 300 feet above tide water. This splendid object of art embodies a grand idea. It will stand at the foot of our great commercial metropolis as the symbol of a political movement that began on this Continent, but is destined to flash its light over the whole world. It is also a symbol of political progress. We are in a world movement that has not yet produced its best men or form of government. The evolving forces never go backwards; and in the struggle of life the best wins. It is a movement that is slowly working the barbarism out of our politics, bigotry out of our religion. Science is hopeful. Religion is hopeful. Government is hopeful. The energies of unspeakable possibilities lie before us, and

"The higher mounted mind still sees the morning spread
The Silent Summit overhead.

Beach Mining.

At several places on the California and Oregon coast beach mining for gold is carried on. In New Zealand a considerable amount of gold is procured from the beaches. Near Charleston is a settlement of Shetlanders whose time is divided between small farm cultivation and the working of fine gold from the sea sand, which, after heavy weather, is easily got at, and found to be highly auriferous. These beach claims are deemed quite valuable. The working results of the claims are various, much depending on the weather.

The engraving given herewith shows a party of Shetlanders working the black sands on the beach near Charleston. They use the peculiar New Zealand beach-box, shown in the engraving. Water is brought into the rifles by means of hose at the rear end.

Many of the "beach-combers" are of the opinion that the gold on their claims comes from the depth of the sea during the storms, and not from the inland workings, as many others suppose. It is, however, a difficult question to determine.

A DISPATCH dated Guaymas, 28th instant, says: Quite a party of Mexicans, most of them capitalists, have arranged a trip to the new gold mines on the Antonio. Careful investigation shows that the first parties who went on the gold fields failed to prospect beyond the immediate reach of water. The largest nugget yet brought from there was shown yesterday, weighing some four and a half pounds. All the American miners who have the means are going back.

The damage by fire on the Island of Gutajewsky, at the north of the Neva is now estimated at 10,000,000 rubles.

lies. It shows that we are in the Gulf Stream of Time. And the fact is undeniable, that as fast as the nations of the earth come upon a certain plane of civilization they feel in their veins the warm pulsations of civil and religious liberty. John Stuart Mill, Herbert Spencer, Walter Baghot, and, indeed, all the great writers on the political questions of the ago, admit the fact. Even the crowned heads of Europe confess it, and only hope to guide the movement a little while longer, relaxing the reins of absolute power as slowly as they can. Forty years ago M. D. Tocqueville said that he did not believe that a democratic form of government was the best thing for the world, but

CORRESPONDENCE.

English Investments in Pacific Coast Mines.—No. 6.

The Sutro Tunnel and English Capital Origin, and Early History of the Enterprise.

[Prepared for the MINING AND SCIENTIFIC PRESS BY H. DREKOOT.]

Although the Sutro Tunnel company is a Nevada corporation, it may for the purposes of this writing, be properly treated as an English concern, inasmuch as English capitalists have furnished nearly all the money required for prosecuting that work, and have almost from the first controlled the affairs of the company. The object of this enterprise was the construction of a tunnel designed to intersect the Comstock lode at a depth of 1,600 feet or more, and to be used for ventilation, drainage and working purposes. The originator and active promoter of this project was Adolph Sutro, whose name it bears, and who, conceiving the idea as early as 1861, began soon after agitating the subject, though no steps were taken looking to the inauguration of active measures until 1864. In the fall of that year, Mr. Sutro applied to the Legislature of the State of Nevada for a franchise, with right of way for such tunnel, which, in the month of February following, was granted to the applicant and his associates. This accomplished, a company was formed for undertaking this formidable work, some of the large mine owners and prominent citizens of Nevada being on the Board of Directors. While there were so connected with the company at the start, some of the more influential citizens of the State, to Mr. Sutro belongs the merit of first moving in the matter, though the idea of its importance is said to have been, in the first instance, suggested to his mind by others.

How He got the Original Idea.

Now, Mr. Sutro was not himself a mining engineer, nor even a practical miner. He had never been to Freiberg, and knew little about driving adits, drifts, crosscuts, or other underground works. He had been brought up to other pursuits, and had, till the time of his emigrating in this enterprise, been engaged in the laudable, because necessary, occupation of furnishing to our tobacco snuffing, tobacco chewing and tobacco sucking population enough nicotine to enable them to digest their virtuous. With the rush of emigration to Washoe, he had gone over to Virginia City for the purpose of establishing there a branch house in his business. Sojourning at this active center of mining, he happened to overhear one day some educated engineers discussing the question of a deep-dyng tunnel to drain and work the Comstock lode, citing, in the course of their conversation, the utility of such works, as demonstrated at various points in Europe. From the hint so thrown out, Mr. Sutro, it is alleged, gained his first idea in regard to a scheme of this kind. Now that it may not be supposed that Mr. Sutro was eaves-dropping on the occasion alluded to, it should be explained that the Washoe hotel of that day was a flimsy concern, consisting of a huge sheet of cotton-drilling stretched over a light wooden frame, so fluffy and loose of texture that the occupant of one apartment could not help overhearing what was being said in another, whether adjoining or some distance away. So, if Mr. Sutro did hear what these gentlemen from Freiberg, Clanshal, or elsewhere, happened to be talking about, it was no fault of his, nor was there any impropriety in his appropriating and acting on the suggestion so thrown out, even if he did do this, the tradition being rather apocryphal, anyhow. But however Mr. Sutro first became possessed of this idea of driving a tunnel, he certainly managed to get it, and what was more, managed to make a good deal out of it in the end.

The Mine Owners First Favor and Then Oppose the Project.

The leading mining companies on the Comstock lode were at first so favorably impressed with the utility of the proposed tunnel, that they contracted with Mr. Sutro to pay him a royalty of two dollars per ton for all the millable or marketable ore taken from their mines, after the work was finished, Mr. Sutro binding himself to have it completed by a certain date. In 1866, Mr. Sutro procured an act of Congress to be passed, confirming the right of way granted to him by the Nevada Legislature. This act also empowered him to purchase, at a nominal price, several thousand acres of land at the mouth of the tunnel, donated to him large sections of any mineral bearing lodes that his tunnel might intersect, and made "it obligatory on the mining companies to pay the stipulated royalty, since, by compromise between the parties, reduced to one-half."

Meantime, Mr. Sutro, though he had succeeded in getting nearly \$1,000,000 subscribed for the stock of his company, delayed active operations, no work having been done upon the much talked of tunnel till near the end of 1869, when a beginning was made with a small force of men. Distrusting Mr. Sutro's ability to get through with the work by the time agreed upon, the mining companies sought to repudiate their contract with him, a movement that pre-

vented Mr. Sutro from getting any more subscriptions for his stock, many refusing to take shares already subscribed for. Then, too, the mine owners had begun to think that the tunnel might not be so very useful after all. They had by this time equipped their mines with powerful hoisting works, whereby the lifting and lowering service could be performed speedily and cheaply. They had erected mills near by and a railroad had been projected for carrying their ores to the Truckee, where, with water power, they could be crushed at a small cost, the returning cars bringing in fuel, lumber and other supplies. Out of this aspect of affairs, differences arose between these parties, which, as neither showed any disposition to yield, grew at last into open hostilities; the result of which was to destroy all chance of Mr. Sutro's raising the money necessary for building his projected tunnel, in this country. To canvass the merits of the contest waged between these parties, would require more space than could here be spared for that purpose; suffice to say, it was bitter and protracted, Mr. Sutro carrying on the fight with great persistence; tact and energy. That he met with partial defeat and was forced to apply elsewhere for financial aid, is no disparagement to the justice of his cause or the ability with which he maintained it.

He Goes to England and Makes a "Raise."

Reduced to this strait—his last hope of raising money on this side extinguished, Mr. Sutro packed his valise and taking his franchises and subsidies hid him to England to see what, if anything, could be done with these valuable muniments over there. Arrived in London, conditions seemed to favor the object of his mission. The British people had by this time heard much of the Comstock lode. They had long desired to become sharers in its great wealth, but interests in these mines had been advanced to such terrific figures that they could not think of buying "feet" at the then ruling prices. But here was now an opportunity to acquire valuable interests in the great Washoe lode at a moderate outlay, there being even a chance of capturing the whole thing in the not remote future; for, Mr. Sutro had demonstrated that whoever controlled the tunnel would be able to control the mines also—in other words, the owners of this structure would eventually become the owners of the Comstock itself.

Now, Mr. Sutro is a good talker, he may almost be said to be a natural orator. Few men are better able to present a case of this kind in a forcible and taking manner. With a large brain and a cheek of chilled iron, nothing discourages, nothing disconcerts him! Imaginative, self-reliant, extravagant in his statements, even reckless of facts, he talks on with a placidity, audacity, plausibility and fluency that, if it does not always confound an opponent is very apt to captivate an unthinking hearer.

That a man so gifted in his peculiar and off-hand way should have favorably impressed our English cousins and even succeeded in taking them in badly is not very strange. Besides, the person of the Albion had not as yet been much lacerated by the claws of the American "wild cat," wherefore, he stood then in less dread of the ferocious beast than he now does. This feline was then a mere kitten in his Washoe lair, having scarcely as yet gotten his eyes open.

What further tended to recommend Mr. Sutro and his cause to the good graces of the average Englishman was the fact that he came among them in the guise of a persecuted and injured individual—a sort of Columbus, seeking aid to discover a new world—a prophet as it were, without honor in his own country. Now however John Bull may sometimes show himself a little brusque toward a neighbor, he is notoriously a lover of fair play, especially where its enforcement and a tolerable interest on the investment go together. So, when Mr. Sutro related his tale of woe, recounting how he had been wronged and abused by the "blasted Yankees," the sturdy Briton listened with many expressions of sympathy and encouragement. "Av, to be sure!" "quite so, Mr. Sutro, quite so," was disposed to "elp the poor man" in his extremity, "would be 'appy to do the right thing ye know," etc., etc. Mr. Sutro knowing this to be one of the infirmities of Bull, took care to play it for all it was worth, the outcome of some hurried conferences had between our Washoe adventurer and British capitalists being an agreement on the part of the latter to furnish the money required to carry on and complete the Sutro tunnel, the sum named by the projector as necessary for that purpose being about \$3,000,000. This, as Mr. Sutro well knew, would be altogether too little to complete the job, but he knew equally well that these parties, having put in that amount of money, would, as a matter of self-protection, be forced to supply whatever more might be needed to put the work through, and so contented himself with naming such moderate sum. The funds being forthcoming, the bulk of the stock carrying with it control of the management, was transferred to the new shareholders. Mr. Sutro, who retained a certain amount of the stock, was appointed superintendent in the field, and operations on the tunnel, which had up to this time been lagging, were thenceforth pushed with great vigor.

The Work Hurried on and Brought to Completion—Mr. Sutro gets out and Makes Money.

From the time operations were so resumed on the tunnel, which occurred in 1871, they were continued without further interruption till 1879,

when the main adit, 20,489 feet long, was finished. Since that time the company have been engaged driving the lateral tunnels, the one running north and the other south along the Comstock lode, and a little below it. The main tunnel, which approaches the load at right angles, intersects it in the Savage ground at a depth of 1640 feet below the croppings. The two lateral tunnels, which have reached a combined length of some 3,000 feet, are being pushed actively ahead, the intention being to extend them to all the more productive and promising mines on the mother lode. This system of tunnels is, throughout, in good condition, though the work of keeping them so has proved a heavy drain on the company's slender resources, more or less retimbering and other costly repairs being every year called for. The management from the first seems to have been economical, energetic and judicious; even Mr. Sutro's administration could not, in this respect, have been improved upon. The company, while they complain that this gentleman deceived them, in that he sold his stock after agreeing to hold on to it, concede that he managed their affairs well. That Mr. Sutro acted in bad faith in the above particular, seems probable enough, having thrown his entire holdings on the market when at its highest, to the great detriment of the company's interests. Out of these sales Mr. Sutro is said to have realized over two million dollars. The question suggests itself whether or not money obtained by such and kindred means is worth what it costs; some people think it is!

As regards the future,

The Outlook for the Sutro Tunnel Company

Can hardly be considered flattering. The total expenditures of the company to date amount to nearly \$8,000,000. Of this sum over \$1,250,000 consist of borrowed money, secured by mortgage on their entire property. Their revenues from all sources for the year ending March 1, 1883, amounted to \$63,213, of which \$47,627 consisted of royalties collected from the mining companies, the balance being derived from the sale of produce raised on their ranch, the income of real estate in the town of Sutro, and sundry minor sources. The disbursements of the company for the year reached \$100,000, exceeding their income by about \$37,000, which sum was borrowed to meet the deficiency.

The annual expenditures of the company, considering how much it costs to keep their tunnels in order, must continue about the same as at present. To what extent their income may be increased hereafter, will depend mainly on the ore developments made in the lower levels of the Comstock mines, which just now are somewhat promising. Should large bodies of high or even fair grade ore be opened up here, the company might be able to relieve themselves of their present indebtedness, defray current expenses, and possibly pay some small dividends. Failing in such developments, this of course could not be done, and the property of the company would probably be sold to satisfy the mortgage resting upon it. The show for finding any large amount of pay ore in the lodes cut by the company's main tunnel, and owned by them, is not encouraging, notwithstanding their superintendent reports such mineral indications in one of these lodes as, in his opinion, justifies its further exploration.

Taking the most hopeful view of the case the Sutro tunnel must be pronounced a somewhat dubious investment. It is true, the trustees of the company in their last report speak in a rather assuring tone, telling the shareholders that their tunnels are, for the most part, in prime condition, and that the flow of water continues uninterrupted, though there is no intimation that they intend to reservoir this flow and declare an aqueous dividend. Apropos to the above remark it may be stated that this tunnel water is decidedly warm and highly mineralized, which latter is more than can be said of the Comstock ores just at present. Should the venture prove a final disappointment these shareholders will have only themselves to blame. Investing their money in the way they did they could have expected no other issue. How they came to be taken in by a man like Mr. Sutro, despite his fine presence and persuasive methods, is something surprising. The circumstances under which he came to them, a stranger, impetuous and without credentials, were certainly enough to have excited suspicion and put them on their guard. The man's evident inexperience in mining, the story of his grievances, in short, every incident and fact connected with his advent in London, amounted to a broad enunciation of the legal maxim, "caveat emptor." But, however this tunnel may disappoint the luckless shareholders, it has probably caused no disappointment to Mr. Sutro himself. It has, no doubt, accomplished all the projector ever expected it to do, having drained the Comstock lode to a depth of 1,600 feet, and the pockets of the English investors to a much lower level.

THE MECHANICS' FAIR.—The price of tickets for the next Mechanics' Institute Fair will be: Double season ticket, admitting two, \$5; single, \$3; children's season, \$1.50; apprentices, \$1.50; adult single admission, 50 cents; children, 25 cents. To members of the institute in good standing—that is, those not in arrears for dues—double and single season tickets will be sold at half the above rates. The Directors believe by this reduction to greatly increase the membership of the Institute, which costs but one dollar to join and fifty cents a month for dues.

Arctic Currents.

Along the Alaskan and Siberian Coasts.

[Abstract of a paper read before the California Academy of Sciences by Captain C. L. Hooper, of the U. S. Revenue Marine.]

On account of the varied and extensive duties assigned to the *Corwin*, and the limited time in which to perform them, a regular connected series of current observations in Behring strait was not taken as it was hoped to do. It was my intention to return for that purpose, after dispatching a sledge party along the Siberian coast early in June. But the rough treatment received by the vessel in the ice-pack, resulting in the loss of rudder and other damage, necessitated a change of plans. It became necessary to seek a place of comparative safety with the vessel where the rudder might be repaired, and, to entrust the current work to a boat's crew, left for the purpose on the West Diomed, an island in Behring strait. Unfortunately, the boat's crew accomplished nothing. Owing to boisterous weather, the boat could not be launched. So much time was consumed in making the necessary repairs, owing to the fact that all the harbors were still frozen up, and we were compelled to make them at sea, that I did not feel justified in remaining longer in the vicinity of the straits, but pushed on to the northward as fast as the ice would permit. Consequently, we were limited in our

Current Observations

To such as could be made, from time to time, by noting the drift of the large masses of ice by comparison of the ship's position, as shown by dead reckoning, and that shown by observation, and by noting the velocity and direction of the current when at anchor. And as we remained at anchor but little, the latter class of observations were seldom taken, and never in a sufficiently connected form to be of much value. Many of our observations were taken in the vicinity of the ice-pack, and as this pack where found occupies about one-third, and in many places one-half, of the entire depth of the shallow Arctic sea, it exerts as much influence on the surface currents as a body of land of the same area, and as the pack, or that portion of it which we are able to observe, is constantly changing its position—not only from month to month in the same season, owing to the destruction of the ice by melting, difference of prevailing winds, etc., but also varies its position from season to season according to the amount of ice formed during the previous winter—it will readily be seen that the consequence is constant change in the force and direction of the current, and the result of one set of observations in the vicinity of the pack is but slight indication of what may be found by the next observer.

In addition to these constant changes in the

Vicinity of the Ice Pack.

Other difficulties are encountered in making observations on the currents, while a vessel is cruising from place to place. Owing to almost constant fogs, it frequently occurs that several days pass without an observation for position. Then, if a difference is found to exist between the position by dead reckoning and that by observation, which can only be accounted for as a current, it is impossible to determine in what part of the ship's track, the current was encountered, how much is due to the tidal current and how much to the wind. There is yet another difficulty encountered by navigators in high latitudes, which bears upon this subject, that of accurately determining the ship's position by observation, even in clear weather.

The same causes interfere with the accurate location of "coast lines," and no doubt account for errors that are often attributed to other causes. When we consider the extent of these difficulties and the fact that they are almost constantly encountered, it will readily be seen that any theory, based upon a few observations taken by one, or even several vessels, from time to time, and in different parts of the Arctic ocean, rests upon slight grounds, and is susceptible of grave error, and that unless supported by evidence of a more definite character, it should be given but little weight. And in submitting the results of my observations, during the cruise of the *Corwin* in 1881, they are subject to these explanations. Perfect accuracy is not claimed; they are, however, in the main, correct, and taken in connection with other facts, to be presented, must have their weight.

On the 28th of May, the *Corwin* anchored at St. Lawrence Island, and

Swung to a strong Northerly Current, Which, however, slackened and indeed, entirely stopped, a few hours later. This change was undoubtedly due to tidal action. Although the wind was from the northward, it was very light and not sufficient to influence the current to any extent.

On the 30th of the same month, while anchored at West Diomed, the ice was observed to be setting to the northward, at about two knots per hour. The wind blowing fresh from southeast with snow squalls.

During the night of June 3d, the *Corwin*, while trying to get south through Behring strait, was met by a large body of ice drifting through into the Arctic ocean from Behring sea, which completely filled the strait; and being compelled to heave to until the next forenoon, the direction of the current was found to be northwest and its velocity about one-half a mile per hour; weather calm.

(CONTINUED ON PAGE 438.)

MECHANICAL PROGRESS.

Damascus Steel.

The term "Damascus steel," or, as it is frequently called, Damascus blades, is applied to a kind of steel which shows a variegated watery appearance on the polished surface. It came originally from Asia, and the scimitars or swords chiefly from Damascus, where the art of manufacturing blades appears to have been best understood. The excellent quality of this cutlery, particularly the scimitars, has long been proverbial; no other steel has been found to equal it in tenacity and hardness. The process by which this steel is worked is not known; it is a secret faithfully preserved among those who are engaged in the manufacture. European artisans and scientific men have endeavored to imitate the Asiatic damask, but with ill success; the form and appearance of the steel has been counterfeited, but its quality has never been equalled. French manufacturers, particularly, have wasted a great deal of time and means in such attempts. The probable cause of the superior quality of this steel is in the raw material, the ore; and it may in some measure be attributable to the skill of the artisan who manufactures the blades. It has been ascertained that the ingots of wootz of which the oriental Damascus is made come from Golconda, and it is, therefore, probable that it is manufactured in the same manner as the Indian wootz. This supposition is strengthened by the great value of the blades, and the peculiarities of the wootz.

Alexander Burns, in his journey to Cabool, tells us that a scimitar was shown him in that city which was valued at five thousand rupees, and two others at fifteen hundred rupees each. The first was forged in Ispahan, in the time of Abbas the Great. The peculiar value of this weapon consisted in its uniform damask; the "water" could be traced upon it, like a skein of silk, the entire length of the blade. Had this "water" been interrupted by a curve or cross, the blade would have been of little value. One of the cheaper weapons was also of Persian make; its "water" did not run straight, parallel with the blade, but was waved like a watered silk fabric. It had belonged to Nadir Shah. The third scimitar was a Khorassan blade; there were neither straight nor waved lines in it, but it was mottled with black spots.

All three blades were strongly curved, but the first was more so than the others. They tinkled like a bell, and were said to improve by age.

Imitations of Damascus steel are made daily, and have been made for the last 50 years, and there is no doubt that some good has resulted from these experiments. The real value of the imitations, however, is quite limited. Damask steel has been made, and is made of such perfectly developed veins, by welding together bundles of small slips of steel and iron, or steel of different kinds, that all imaginable figures which can be delineated by hand have been imitated. The smoothed water, the waved water, a tension of the damask, and the spotted damask, have all been produced; names, letters, inscriptions, leaves and flowers have been represented; but all these pretty things do not make Damascus blades of equal quality with those of Asiatic manufacture. It appears the Persians do not use so much skill in forging, but depend upon the elements. Recent experiments have shown that when blades are cooled slowly, as by swinging them in the air, a damask is produced on steel highly charged with carbon. This, however, is nothing new; for the next best blades to those of oriental manufacture—the blades of Solingen—have been hardened or tempered in that way for centuries. It is certainly the most perfect mode of hardening steel, where tenacity also is desirable.

It is said that one hundred parts of soft iron and two parts of lamp-black, melted together, make a fine steel of great strength. It is also said that equal parts of cast and wrought iron turnings make a fine steel, of damask quality, which is superior for arms and edged tools.

There is no doubt that, by such means as the foregoing, an imitation of the appearance of damask steel may be effected; but it will depend entirely on the quality of the steel, the iron, the cast iron, the lamp-black or the crucibles whether the resemblance will extend to the quality of the steel.

Damask veins may be made to appear on the surface of polished steel by washing it with a thin solution of sulphuric or muriatic acid, which will dissolve the softer parts of the steel first on those points which contain the least carbon; after which the steel is washed in fresh water, and oiled or waxed. It is not known whether or not the Orientals bring out their damask in a similar way. Steel is sometimes buried underground, often for months together, to improve its quality. May not this be the manner in which the Orientals etch their blades? —Blacksmith and Wheelwright.

Why Iron Chills.

For chilling cast iron, says a writer in the *American Machinist*, different pieces require different treatment, but there is one essential point to be borne in mind, that is, the chill should be covered as quickly as possible. It is impossible to do this too quickly, providing the surrounding parts of the mold will stand it.

The hotter and more liquid the iron, the deeper and smoother the chilled surface will be.

The process of chilling iron involves a chemical change in the part chilled. That part contains carbon in a combined form, while the parts of the casting that are not chilled contain carbon in two forms, graphite uncombined, and combined carbon in a less degree than the chilled parts.

Cold blast iron contains a larger per cent of carbon than hot blast iron, and when liquid cold blast iron comes in contact with a chilling surface, the sudden lowering of the temperature produces the chemical change which results in what is called a chill. The more liquid the iron, the deeper and more complete the process of converting the uncombined into combined carbon. When this change is made, so far as my observation goes, it is permanent. Even remelting does not undo the transformation.

A number of years ago there were made in the shop where I worked several large castings that were chilled from one inch to two inches deep. Some of these castings were condemned for imperfections. They were made from the best of iron—"Richmond" and "Saulsbury"—and the foreman concluded to put the condemned castings into locomotive driving-wheels. They were broken up and cast, and every wheel broke like an icicle when being pressed on the axle.

The castings I speak of were for safes, and one was taken from the sand while red and subjected to the cooling effect of a stream of water. This was done to demonstrate that in case of water being played upon them at a fire there would be no danger. When this one mentioned was cooled by means of water, it was broken up like a piece of ice; in fact, a laborer, with hob-nailed shoes, literally granulated portions of it beneath his feet. This showed the chemical change going on to the end of the cooling process.

Now, then, cold blast iron is the strongest of irons, yet it contains combined carbon in a greater degree than hot blast iron, which proves that, to a certain extent, its presence increases its tenacity, and beyond that it decreases the strength of the metal.

PHOSPHORIZED NICKEL.—Pure nickel, after melting and casting, generally holds a greater or less quantity of oxygen in solution, and the metal is brittle. To hinder the injurious effects of the oxygen, it is necessary to incorporate in the melted nickel some substance which has a strong affinity for oxygen, and also for the nickel itself. J. Garnier finds that phosphorus serves both of these purposes very satisfactorily, producing effects analogous to those of carbon in iron. If the phosphorus does not exceed three-tenths of one per cent, the nickel is soft and very malleable. Above this quantity the hardness increases at the expense of the malleability. Phosphorized nickel, when alloyed with copper, zinc or iron, gives results which are far superior to those that are obtained from the same nickel when not phosphorized. By means of the phosphorus, Garnier has been able to alloy nickel and iron in all proportions, and always to obtain soft and malleable products. The contradictions of illustrious chemists are thus explained, some saying that such alloys were brittle, others that they were malleable. The latter had alloyed the nickel to phosphorized iron.

METALLIZATION OF TIMBER.—The Rubemnick process for metallizing wood consists in first immersing it in a bath of caustic alkaline lye, in which it is allowed to remain for two or three days, according to the degree of permeability of the wood, at a temperature of 167° to 194° Fahr. From this bath the wood passes to another of hydrosulphate of calcium, to which is added, after twenty-four or thirty-six hours, a concentrated solution of sulphur. Here it remains for about forty-eight hours, at a temperature of 95° to 122° Fahr., and, lastly, for from thirty to fifty hours, the wood is immersed in a solution of acetate of lead at the same temperature. The timber, thus pickled, is allowed to dry, when it is said to be susceptible, after burnishing, of a high polish, and even a metallic luster, which is more brilliant if the surfaces of the wood have been previously rubbed with lead, tin or zinc plates, and then polished with a glass or porcelain burnisher. Treated in this way, the wood may assume the appearance of a metallic mirror, being at the same time hard and very strong.

HOLLOW BRICK WALLS.—The question is often asked—"Are hollow brick walls better and stronger than solid walls?" For instance: Brick building, four stories, first floor earth; second story, machine shop, say fifteen tons; third story, stove shop, say nine tons; fourth story, light goods, say six tons. The *Scientific American* answers as follows: The tremor of factories is more severe upon hollow walls than upon solid walls, unless more than the quantity of material in a solid wall is put into a hollow wall. It is the weight of material in the walls that counteracts tremor and swaying. A hollow wall under any circumstances for factories should be thoroughly bonded at small intervals.

MR. J. B. SHERMAN, of Boston, is reported to have recently concluded a series of experiments upon a new metal discovered by him, with a view of ascertaining its adaptability for telegraph wires. The experiments, it is said, have yielded results favoring the adoption of the new material, which is reported to have the appearance of silver, and costs to produce about five cents a pound.

SCIENTIFIC PROGRESS.

Labor and Food.

The human body never ceases to work. Even in the most profound slumber some of the functions of life are going on, as, for instance, breathing, the circulation of the blood, digestion, when there is food in the stomach; and it follows that some part of the nervous system is, therefore, awake and attending to business all the day and night long. In the act of living, some of the substance of the body is being constantly consumed. The amount of work done by the heart in one day in propelling the blood is now estimated as equal to the work of a steam engine in raising 125 tons one foot high, or one ton 125 feet high. We lose in weight by working. Weigh a man after several hours' hard labor, and he will be found two or three, and, in extreme cases, several pounds lighter. If we do not wish to become bankrupt, we must replace by food the amount we have lost by labor. Hunger and thirst are the instincts which prompt us to do this. They are like automatic alarm clocks, which stop the engine at various points to take on fuel and water. In a healthy man as much is taken in as is required to maintain the weight of the body against loss. Nature keeps the account. On one side is so much food spent in work; on the other, so much received into the stomach for digestion. They should balance like the accounts of an honest book-keeper. In an unhealthy person the instinct of hunger becomes disordered and does not sound the alarm, and so the person goes on working without eating until he becomes pauperized; or the instinct works too frequently, and he eats too much and clogs the vital machinery. A calculation of the business done in the body reveals the fact that for a hard working person about 8½ pounds of food and drink are used up daily; some bodies use more and some less, but this is the average. The profit which the body gets on this transaction has been calculated, and may interest our readers. The energy stored up in the 8½ pounds of food ought to raise 3,400 tons one foot high. Most of this energy, however, is expended in keeping the body warm and its functions active. About one-tenth can be spent in our bodily movements or in work. The profit, then, on the process is about ten per cent. This is enough to raise 340 tons one foot high each day. A profit which is quite enough for earning a good living if rightly expended, and it is probably more than most make, but all ought to strive to reach this point if possible. —*Scientific American*.

The Value of Metals.

Following are the names of those metals valued at over \$1,000 an avoirdupois pound, the figures given representing the value per pound: Vanadium—A white metal discovered in 1830, \$10,000. Rubidium—An alkaline metal, so called from exhibiting dark red lines in the spectrum analysis, \$9,070. Zirconium—A metal obtained from the minerals zircon and hyacinth, in the form of a black powder, \$7,200. Lithium—An alkaline metal; the lightest metal known, \$7,000. Glucinum—A metal in the form of a grayish-black powder, \$5,400. Calcium—The metallic base of lime, \$4,500. Strontium—A malleable metal of a yellowish color, \$4,200. Terbium—Obtained from the mineral gadolinite, found in Sweden, \$4,080. Yttrium—Discovered in 1828, is of a grayish-black color, and its luster perfectly metallic, \$4,080. Erbium—A metal found associated with yttrium, \$3,400. Cerium—A metal of high specific gravity, a grayish-white color, and a lamellar texture, \$3,400. Didymium—A metal found associated with cerium, \$3,200. Ruthenium—Of a gray color, very hard and brittle; extracted from the ores of platinum, \$2,400. Rhodium—Of a white color and metallic luster, and extremely hard and brittle. It requires the strongest heat that can be produced by a wind furnace for its fusion, \$2,300. Niobium—Previously named columbium, first discovered in an ore found at New London Conn., \$2,300. Barium—The metallic base of baryta, \$1,800. Palladium—A metal discovered in 1803, and found in very small grains, of a steel-gray color and fibrous structure, \$1,400. Osmium—A brittle, gray-colored metal, found with platinum, \$1,300. Iridium—Found native as an alloy with osmium in lead-gray scales, and is the heaviest of known substances, \$1,000.

PHILOSOPHY OF QUIETING THE WAVES WITH OIL.—Van der Meushrugge reasons as follows to explain the effect produced by a thin stratum of oil spread over the surface of the sea to quiet the water: To increase the surface of a mass of water, a certain amount of force is required, and this force is stored away, as potential energy, in the superficial layer of the water. Also, when the free surface of the mass of water is decreased, proportionate amount of this potential energy is changed into kinetic or actual energy. Thus, when one stratum of

water is brought—say by the wind—over another, the potential energy of this latter is changed into kinetic energy, and a certain velocity is generated. When, however, one stratum of water is brought upon another covered with a thin layer of oil and, consequently, having less potential energy than the first, the amount of force transformed into kinetic is considerably less than that remaining as potential energy. In other words, there would be a continual disappearance of actual force, and this would explain the tendency of the waves to subside much more quickly than when no oil is present. —*Comptes Rendus*.

Nature in Siberia.

"The history of animal and vegetable life on the tundra," says our author, "is a very curious one. For eight months out of twelve every trace of vegetable life is completely hidden under a blanket six feet thick of snow, which effectually covers every plank and bush—trees there are none to hide. During six months of this time, at least, animal life is only traceable by the foot prints of a reindeer or a fox on the snow, or by the occasional appearance of a raven or snow-owl wandering above the limits of forest growth, where it has retired for the winter. For two months in midwinter the sun never rises above the horizon, and the white snow reflects only the fitful light of the moon, the stars, or the aurora borealis. Early in February the sun only just peeps upon the scene for a few minutes at noon, and then retires. Day by day he prolongs his visit more and more, until February, March, April and May have passed, and continuous night has become continuous day. Early in June the sun just touches the horizon at midnight, but does not set any more for some time. At midday the sun's rays are not enough to blister the skin, but they glance harmlessly from the snow, and for a few days have the anomaly of unbroken day in midwinter. Then comes the south wind, and often rain, and the great event of the year takes place—the ice on the great rivers breaks up, and the blanket of snow melts away. The black earth absorbs the heat of the never-setting sun; quietly and swiftly vegetable life awakens from its long sleep, and for three months a hot summer produces a brilliant Alpine flora, like an English flower garden run wild and a profusion of Alpine fruit, diversified only by storms from the north, which sometimes for a day or two bring cold and rain down from the Arctic ice." —*Chambers' Journal*.

OBSERVATIONS ON SOUND.—The following curious observations on sound have been carefully verified by an extended series of experiments: The whistle of a locomotive is heard 3,300 yards; the noise of a railroad train, 2,800; the report of a musket and the bark of a dog, 1,800; an orchestra or the roll of a drum, 1,600; the human voice reaches to a distance of 1,000; the croaking of frogs, 900; the chirping of crickets, 800. Distinct speaking is heard in the air from below up to a distance of 600 yards; from above, it is only understood to a range of 100 yards downwards. It has been ascertained that an echo is well reflected from the surface of smooth water only when the voice comes from an elevation. Other similar phenomena connected with the transmission of sound have been observed, but the results disagree, either from inaccuracy in the observations or from the varying nature of the circumstances affecting the numbers obtained. Such variations occur to an extent of 10 per cent. to 20 per cent., and even more. The weather being cold and dry, or warm and wet, are the chief influencing causes. In the first place the sound goes to a greater, and the second to a lesser distance.

PERMANENT LAMP ATTACHMENT.—MR. C. H. Stearns, F. R. S., has recently introduced an interesting application of the incandescent lamp to microscopes. A small Swan lamp of two or three candle power is permanently attached to the microscope, and serves in place of the ordinary oil lamp, over which it has the advantage of requiring no cleaning, giving off no smell or much heat, and yielding a purer light. The great care and facility with which the lamp can be adjusted is beyond comparison with the ordinary gas or oil flame, especially when the light has to be shifted to above or below the stage for illuminating opaque or transparent objects. Condensers may also be got rid of by its use. The light of the lamp is controlled by a small resistance coil, and two or three Grove or Bessmer cells are sufficient to work it.

IRON AND STEEL MAGNETIZED BY BREAKING.—At a recent meeting of the Society of Physical and Natural Sciences, Karlsruhe, M. Bissinger made a communication on the magnetization of bars of steel and iron when broken on the machine, serving to test them. The phenomenon is not due to elongation of the bar, but to the actual breakage; and both parts are converted into two magnets of sensibly equal power. The shock and trembling of the metal on breaking, is probably the cause of magnetization. According to Professor Hughes' recent experiments, in the testing machine, the bars are placed vertically, and the south pole is formed at their upper part. The different iron objects near the machine, at the moment of rupture and vibration, are also magnetized, but to a less degree.

GOOD QUARTZ.—Plumas *National*, June 23. Quartz prospecting is all the rage on the East branch and some good ledges are being opened. The work on the Hallsted ledge on Rich gulch, proves that it is rich and of vast extent, and several other fine cropings have been found in the same locality. One day last week Mr. McPherson, of Meadow valley, found what is supposed to be the northwest extension of the Hallsted ledge, on the Deadwood side of the mountain, and he has quartz which shows fine gold and is very rich. Fred Lewis has some good quartz, and the indications point to a large and lively quartz mining camp at that place in the near future.

Mining stocks have been rather dull for a week, and the brokers adjourn over from Saturday until next Thursday. Our tables show the slight fluctuations in the market. All interest now centers in Union Consolidated. Although the streak of ore cut by the crosscut in the first winze and Sierra Nevada crosscut on the 3,000 level is spoken of as being four feet in width, the quartz formation at that point is really much wider. There is about four feet of solid quartz, then quartz and porphyry are sandwiched in for several feet to the west, quartz predominating. This appears to be the top of a new formation that has no connection, as far as can be seen, with the ore vein cut on the 2900 level. How far the west crosscut may yet have to go before reaching the ore body for which it was started nobody can say, as no one can tell what changes of dip may have occurred in the walls of the vein below the 2,900 level. When cut above the vein showed every indication of being the top of an ore body. In the Union ground a raise was made on it, and it was found to wedge out at the height of twenty feet, while it seemed to be rapidly widening in going downward. This ore vein is about 500 feet east of the west wall of the Comstock lode, and it is worthy of note that the point where the big bonanza in the Consolidated Virginia and California was first cut, at the south end, was about the same distance from the main west wall. The west wall of the ore streak, where last seen on the 2,900 level, was going down almost vertically. The *Enterprise* thinks there is nothing to prevent it turning for a time toward the west, for should it go straight down it would not reach the west wall of the lode much under 500 feet. All the big ore bodies of the Comstock have been found to go down straighter than the main west wall of the lode, and have eventually brought up against said wall. The present prospects are well out towards the middle of the lode.

San Bernardino.

BORAX DEVELOPMENTS.—*Calico Print*, June 23: Work on the borax claims in East Calico which were recently purchased by C. L. C. & Co. has been progressing ever since the company obtained possession of the property. Several men are employed in taking out borax. The deposits that are being opened up are large and of a high grade. We learned from F. M. Neel, the foreman, that a building 14x40 ft. is to be erected on one of the claims in a few days, and that it was not yet decided how soon reduction works will be built for manufacturing the borax.

LOVE STAR.—This claim is situated in West Calico about two and a half miles from town, and has recently been bonded by H. H. Spencer, of Los Angeles. Some work had already been done on the mine including a tunnel and an incline shaft of 30 ft. Mr. Spencer intends to put on a force of men and proceed to open up the mine expeditiously and in good shape.

INVISIBLE.—Mr. Whitmore has, up to date, been quite successful in the development of this fine property. The returns from ore milled have been quite satisfactory, and it is expected that the 20 tons now on the dumps will realize more bullion to the ton than any ore yet milled.

TAGGART.—Two men are at work in this promising mine taking out some exceedingly rich ore filled with red and wax silver. They are working on the west side of a bluff, and have opened up a fine body of ore by sinking an inclined shaft 20 ft. The owners are very much pleased with their prospects. They will soon ship what ore they have on hand, but will shut down operations on the mine in a few weeks until the hot weather is over.

GARTFIELD.—Operations in this mine continue without any diminution in the richness of the results. Sinking and drifting are daily advancing in the midst of fine bodies of ore. The ore is free milling and is extracted and loaded on the teams without much expense. Over 200 tons of ore have been hauled from this mine to the Oriental mill, the pulp assays of which average 110 ounces to the ton, and which, it is thought will net above \$20,000.

Sierra.

GOLD LAKE.—*Mountain Messenger*, June 23: All the claims in this rich mining district are yielding large returns this season. Cox, Myers, Dorsey and others are having good cleanups. Mr. Dorsey brought a nugget, worth \$60 to Sierra City, the other day. Last week, Thursday and Friday, Foss & Den-nire picked up on the bedrock over \$3,000 worth of specimens, one valued at about \$1,400. The water season has been very short.

SIERRA BUTTES.—*Sierra Tribune*, June 22: The Sierra Buttes mine at Sierra City is undoubtedly the best managed mine in the State. For 14 years, during which time the present company has owned the property, there has been a monthly dividend declared regularly. Tunnel No. 8 is now in a distance of 4,200 ft. From this tunnel to No. 7 above not a pound of ore has been disturbed. No. 9 tunnel, several hundred feet still lower down the mountain side, was started last year, and at this time is in 2700 ft. The ledge was tapped a few weeks ago and the course of the tunnel was changed somewhat in order to follow the vein. There are several distinct pay chimneys of ore in the mine and it will be necessary to run the lower tunnel into the hill one and a half miles to reach all of these. Although the mine has been worked on a mammoth scale for over 20 years, it would seem that work was just beginning and it is impossible that a century would give time enough to exhaust the immense bodies of ore that are being opened out. Dr. Sawyer paid a visit to the root drift mine last Sunday. This mine is located a couple of miles east of Sierra City. It is strictly a home enterprise, a large amount of money having been expended by residents of that section in developing the claim. The channel was encountered a short time ago and gravel that is being taken regularly now yields handsomely. Six dollars was taken from two pans of dirt that was picked up out of the dump Sunday. Supt. Shaw started the work of sinking in the main shaft of the Marguerite mine last week. The 20 stamp mill is pounding away day and night on ore that will probably average \$15 per ton. Messrs. Abbe, Sawyer & Flint, of Sierra City, are driving ahead a tunnel on their ledge, located in Lady's canyon. It is said that 500 lbs of gold have been taken out of the Four Hills mine during the past month or two. This sounds big to persons who do not understand that Sierra county is capable of showing the richest quartz mines in the world. The Hog canyon quartz mine is to be started up soon. There is a mill on the property. Harry Warners owns the Mountain quartz ledge, located east of the Sierra Buttes lode. Harry has expended about \$25,000 in placing the claim in shape to work, and now he is confident that he can show as fine a piece of mining property as there is in the State. Keggleson & Mowry's hydraulic mine at Craycroft Hill has yielded handsomely this season.

MAY BUY THE GOLDEN GATE.—There is very strong talk of organizing a company of Sierra county men to operate at the Golden Gate mine, at Alleghany. The proposed plan is to issue 20,000 shares of stock at \$1 each, \$10,000 would suffice to pay off all lawful claims against the property; \$5,000 would pump out the mine and place things in shape to develop the bonanza that is certain to be found. As no definite action has been taken in the matter yet we can not give any further particulars at present. The successful working of this mine would prove a greater benefit to southern Sierra than any other enterprise that could be inaugurated.

Shasta.

WHISKYTOWN.—*Cor. Shasta Courier*, June 22: The Blair, Saulan & Co. quartz mine is bonded to the Phoenix M. Co. for \$4,000. This mine lies one-fourth of a mile west of the Phoenix and has good returns. B. S. & Co. had to stop work on account of water. Evidently, this is a good mine, but it requires capital to work it.

Trinity.

BULLYCHOOP.—*Trinity Journal*, June 22: Quartz interests in Bullychoop are said to be looking remarkably favorable of late, which reminds us that a promised communication from that district relative to its mines has not yet been received. Henry Burns, our thoroughly practical hydraulic miner, formerly superintendent of the McGillivray mines on Trinity river, is firm in the conviction that the mines of Trinity county promise as well as any on the coast.

NEVADA.

Bullion District.

THE OUTLOOK.—*Cor. Eureka Sentinel*, June 26: The camp does not vary much from other new camps. We have among us two classes of men. One is the prospector and the other is the miner, who wants a job at \$4 a day. Men of this latter sort will have to wait. They are not needed for the present. They will come into requisition after the risk and pioneer work are over, and the road is smoothed out for them. Several of them are lying around the saloons and telling each other the bloody camp has nothing in it. The prospectors on the other hand, are putting in their best ticks, with the prospect of a paying harvest in the future. They are putting ore in sight. They have done enough work to satisfy themselves that there is material here for a big, prosperous camp. Men with a little capital can do well here now, as the boys haven't got up to fancy figures yet. The Limestone Silver Mining Co. have just begun work on their property. They have 10 inches of high grade galena and carbonate ore going straight down into the line. Their progress is being eagerly watched. The formation is favorable for large deposits and the indications first-rate. The Kettle mountain folks are talking of building a wagon road to the Limestone Co.'s mines, in order to get shipments of ore for their new furnaces to run on.

Esmeralda District.

UNDERGOING REPAIRS.—*Esmeralda Herald*, June 22: Wednesday we visited the Silver Hill mill at Gregory flat. The mill is being thoroughly overhauled and repaired by H. Marden, Billy Ball doing the work with the aid of John Vernon, A. Hull and Johnny Booker. Two new pans are being put in and two old ones made as good as new. Five new tanks have taken the place of the old leaky ones, and blind drains cut to carry off what water may ooze out. The engine is receiving an overhauling. An addition has been made to the building for a blacksmith shop. Eugene Godat is excavating on the outside for a slant tank. New belting will take the place of the old, and when all the alterations and improvements are completed, the mill will be equal in every respect to any 10-stamp mill in the State. As near as can be judged at this time, it will be ready to crush about next Thursday or Friday.

Eureka District.

RICHMOND.—*Eureka Sentinel*, June 16: There was considerable flurry on the streets yesterday, occasioned by the report that an important strike had been made in the Richmond mine. Through inquiry from those who are at headquarters and are in a position to know, and who, also, have no disposition to equivocate, we learn that there is "nothing in it." The condition of the mine at present, however, is not discouraging. On the contrary, the outlook is hopeful. Small bodies of ore are being found from time to time that keep the mine up, while the indications are favorable for finding an ore body. Very thorough and important prospect work has been done during the last 12 months, with the confident expectation on the part of the present management of ultimately striking something big on the lower levels.

Safford District.

PURCHASING ORES.—*Safford Express*, June 20: The Onondaga Mining Co. gives notice that it will hereafter purchase all ores on the dumps at Safford which assay \$25 per ton and over. This is encouraging news and demonstrates the low quality of ores that can be worked in this district, especially when it is taken into consideration that these ores have to be shipped to Salt Lake City, a distance of several hundreds of miles and there worked at a profit. This will be a great help to miners in our district who may be in need of money and have not the time or means to ship their rock away.

SHIPPING ORES.—*Eureka Sentinel*, June 16: The Onondaga mine at Safford will commence shipping ore to Salt Lake on Thursday next, a contract having been let yesterday to C. H. Hall, of Beowawe to haul the same from the mine to the railroad. The ore will be taken across the river in a row-boat until the water becomes low enough to allow fording. This is encouraging news for our neighboring district, as we are informed that the mine can furnish steadily 30 tons a day for an indefinite period.

Taylor District.

FINE PROSPECTS.—*Cor. White Pine News*, June 22: Your correspondent visited several of the mines of this district to-day. I was more than pleased at the many fine prospects to be seen in the camp. The first I visited was the Old Brown Bull, owned by Wm. Pryde, Bob Simpson and another partner. The mine is looking well and they are taking out some good ore. They have all the prospects of developing a first-class mine. Hon. A. J. Blair is sinking a shaft, and the indications are that he will soon show up a mine second to none in the district. But little work has been done, though its owners have refused \$16,000 for it. It is owned by John Verzan and two partners, who are at present engaged in the butcher business. There are lots of idle men here, though I believe all the Cherry creek boys are at work.

Tuscarora District.

ELKO CON.—*Times-Review*, June 21: Drift No. 4 has been extended a distance of 15 ft the past week, the last 3 ft being in vein matter on foot wall of west lateral vein. Will discontinue development in this portion of the mine for the present and immediately commence to straighten and timber shaft No. 2 for the purpose of improving our hoisting facilities.

NAVAJO.—Have started an upraise to connect with the 350 level. Other work in and about the mine progressing as usual.

GRAND PRIZE.—West drift on the 700 level is in 334 ft. Joint winze below the 700 level is down 31 ft. The upraise from south crosscut on the 500 level is connected with the 400 level and have commenced stopping from it. The ledge is about a foot wide of fair grade ore. Mill is running on company ore now.

INDEPENDENCE.—The vein shows a width of 3 ft, but no ore. Drift north, 300 level, extended 27 ft; total length, 324 ft. No material change in the formation.

ARGENTA.—West drift from ledge has been extended 16 ft; is in ledge matter giving low assays. Stopes are producing a little ore.

NORTH BELLE ISLE.—Good progress has been made in advancing the drift and upraise on the 300 level. During the next week upraise will connect

with the 150 level. Formation in the drift going south is looking favorable for mineral.

Washoe District.

HALE AND NORCROSS.—*Enterprise*, June 23: The winze below the 2600 level is down about 35 ft. It still shows some good ore on the west side of the bottom. Progress is slow at this point, as much of the air is being used at the winze which is to connect the 2400 and 2600 levels.

SIERRA NEVADA.—On the 3000 level the joint Union Con. west crosscut is out from the joint winze a distance of 46 ft. The face is in a mixture of quartz and porphyry. This material is very hard and breaks out poorly in blasting. How far it may be to the ore vein no one can say; as the distance depends on the dip the ore may have taken below the 2900 level.

MEXICAN.—On the 3100 level the north lateral drift is being advanced as rapidly as possible to connect with the deep winze of the Union Con. and Sierra Nevada, which will presently be sunk to the 3100 level. This connection will be one of great importance, as it will cool and ventilate an immense amount of new and very interesting ground.

OHMR.—Good progress is making in the work of repairing the old Central tunnel. This tunnel starts on Mill street, under the lower railroad bridge, and will come in about 160 ft below the surface at the old Mexican shaft. When repairs are completed the ore now taken out at the surface at the croppings will come out through the tunnel to Mill street. The ladders in the main incline are being repaired.

YELLOW JACKET.—The Sagebrush, second and third level are yielding about the usual quantity of ore. They will soon have the west drift from the fourth level open. At this point it is expected that a good deal of paying ore will be found.

ANDER.—Considerable prospecting is being done and some paying ore is being extracted.

CALIFORNIA.—The south drift on the 2900 level is being advanced as rapidly as possible, as also is the west crosscut on the same level.

NORTH GOULD AND CURRY.—Good progress is made in the sinking. The rock at the bottom of the shaft is vein porphyry, with frequent streaks of quartz and seams of clay.

CROWN POINT.—The upper levels are still yielding a considerable amount of paying ore, with the chance of finding more in the prospecting sections.

White Pine District.

RUNNING.—*Cor. White Pine News*, June 26: The Smoky mill is running finely—everything about it seems in first-class order. They pump back the water from the tailings dump after being used, with a neat little arrangement put up for that purpose. The new pans are doing all that was expected of them. A nice stream of water is running from the new tunnel in Monomoke hill. Two teams, in charge of Alex. Muir, are now hauling ore from the hill. Some very fine ore is being taken from the Safford mine. A narrow streak of very high grade ore is reported to have been struck in the Truckee.

ARIZONA.

NEW SMELTER.—*Silver Belt*, June 16, Mr. Fitch, an experienced smelter, has leased the old New Era mill property, from Mr. Duryea, with the intention of erecting a smelter for the treatment of argentiferous galena ores. There is more than the possibility of success in the scheme, as there is a great quantity of such ores rich in silver, in this district.

PECK DISTRICT.—*Cor. Arizona Miner*, June 22: A party of six, including your correspondent, took a trip to the Black Warrior mine last week. The party was shown through the mine by the genial and accommodating Supt. Mr. Eamans, who spared no efforts to make the visit as enjoyable as possible. Arriving at the mine we found everything hustle and activity. The large pile of ore on the dump was examined and found to be very rich. Then we proceeded to examine the mine. After going through a tunnel 250 ft in length we came to the hoisting works, when we were let down in the bucket to the 50 level, from which place we inspected numerous tunnels and saw great quantities of very rich ore. After wandering about for some time in the bowels of the earth we became desirous of once more seeing the lovely sunshine and beauties of nature on the surface. We were then hoisted up in the same way we were let down, and after passing again through the 250 tunnel we found ourselves once more on the surface of the earth, feeling quite good over our first experience in mining. The hoisting works on the Peck mine will be completed in a few days, when the true development of the mine will be commenced with great energy.

COLORADO.

DUMONT.—*Georgetown Courier*, June 22: Drifting has commenced both east and west on the California lode, in the Lincoln tunnel. The vein shows up finely as the drift progresses. The whole vein, for 20 inches in thickness is being saved. Considerable smelting ore is interspersed through the vein. Quite a number have been soliciting a lease, but the company are too wide-awake for such sharks. This company have expended too much money in running their cross-cut tunnel to intersect with this large and promising vein, to give the cream of it away to every Tom, Dick, or Harry that comes along. The lower level running west now shows a vein of solid smelting ore 20 inches in thickness; mill dirt 25 inches thick. One car load of smelting ore was shipped last week to the public sample works at Black Hawk. The Mansfield mill is being filled up with the mill dirt from the Albino mine. The Lee mine is looking splendidly. Sinking the shaft upon the Milton still progresses.

IDAHO.

PLACERS.—*Idaho World*, June 16. Messrs. Donahue & Murphy are having good success so far this season in their hydraulic placer mining ground above Bear Run, on the Gold Hill side, near Elk creek, just below Mann & Co.'s hydraulic, hill placer mining ground. They are running one hydraulic with a fall of 120 ft, and with about 300 inches of water, and are running night and day shifts, with four hands by day and three at night.

BOULDER CREEK.—M. W. Johnson, General H. R. Caulkins and J. A. Greenlaw, a buyer and operator of mines from Park City, Utah, came to town

this morning. These gentlemen are mine investors and are well-known on the coast, having been connected with some of the larger negotiations made in many mining camps. Mr. Greenlaw is largely interested in Leadville mines and in their management. These gentlemen have been on upper Wood River many days, and examined all the principal mine locations in Warm Spring district. They are negotiating at present for mine property on Boulder creek, with the intention of developing some of the best mines there, and will invest largely in preliminary work.

EAST FORK ITEMS.—Messrs. Abrahams and Fainer, two Colorado and New Mexico prospectors who came to Wood river a couple of weeks ago, concluded to try their luck on the East Fork of Wood river. Last Friday they struck a prospect on the hill adjoining the Ben Butler, Lizzie Lemp, and Elbe Bronide. They called it the Colorado, made a location, and began work. Since then they have made a cut in the ledge, exposed three strata of galena, each four inches wide, and extracted over 1,000 pounds of ore which assays 91 ounces silver and 75 lead to the ton. They are developing their claim.

OREGON.

NOTES.—*Jacksonville Times*, June 2: Bybee & Newman's claim has been shut down for the season. About \$2,000 was cleaned up recently, which shows that the claim is a good one. L. A. Heberle returned from Josephine county Monday, and informed us that the companies working large claims in that section are getting ready to clean up, as water is beginning to fail. Considerable chrome is being taken out right along from the mines in the vicinity of the low divide of Smith river, for the transportation of which to Crescent city teamsters going down from here can earn \$5.50 per ton. C. W. Burrage and Mr. Pomeroy, representing capitalists of Portland, have men at work prospecting some iron deposits in the vicinity of Rock Point. The outlook is promising and we expect that some important developments will be made soon. The mineral resources of southern Oregon are gradually receiving the attention they deserve.

MONTANA.

SUMMIT VALLEY PLACERS.—*Butte Miner*, June 20: In 1864 when the placer diggings of Summit valley were first worked they were considered very rich; and old timers tell interesting stories of the fortunes which were washed out of the ragged looking gulches which abound south of the city. Placer mining at that time may be said to have been in its infancy, and the methods employed were exceedingly crude, the pan and rocker being the plan most in vogue for separating the precious dust from the gravelly soil. It was supposed that when the soil was worked off to the partially decomposed bed-rock the ground was exhausted; which was a fallacy likely to prove of great advantage to the present owners of some of the old placer claims. A *Miner* reporter recently found two men prospecting an old claim south of the city limits, which was supposed to have been worked out years ago. In his presence one of the prospectors scraped an ordinary miners' spade full of decomposed granite from the surface of the bed rock and panned it out of the spade in a pool of water which had settled in the rocks, getting 55 cents in coarse gold from the single spade full. John Noyes is now working his claim, which lies partly within the city limits and just east of lower Main street, with good results. Hydraulic works are employed for which the Noyes ditch supplies 350 inches of water. A larger supply of water might be profitably used, but the head is good, and with the present supply the banks are tumbled into the stream and thence through the 300 ft of sluice box with astonishing rapidity. Mr. Noyes has earned the value of the decomposed granite on the surface of the bedrock, and after the hydraulic works have washed the soil away, nine men are employed in shoveling it into wheelbarrows and wheeling it to the sluices. Two clean-ups have been made this season with very satisfactory results. Hereafter clean-ups will be made every two weeks, and judging by previous results it would not be surprising if the production for the season amounts to \$30,000 or \$40,000.

A NICE CLEAN-UP.—*Inter-Mountain*, June 20: A gentleman by the name of Wing has been operating the Driscoll sluice box on the tailings of the old Centennial mill for the past six or eight weeks, and a few days since cleaned up 700 pounds of quicksilver and 75 pounds of bullion as a result of the run. The bullion proved to be worth \$10 a pound, and estimating the quicksilver at the market rates, the clean-up was worth between \$1,000 and \$1,200 a very good showing. The concentrations are also saved, which will prove an additional source of wealth from the run.

NEW MEXICO.

SMELTER.—*Southwest Sentinel*, June 20: Silver City needs a smelter as much as she needs a fire engine. The earloads of ore and concentrations which leave our depot each day, should be treated right here on the ground. There is money in this, besides, for the right man. Responsible parties who enjoy the confidence of miners, could make advantageous contracts, right now, for sufficient ore to run a smelter six months or even a year. The Benson smelter is a success both financially and practically. The Albuquerque smelting is doing equally well. Both draw their main supply of ore from Grant county, New Mexico, every pound of which would come to Silver City for reduction, if responsible, enterprising men would put up a smelter here. Who will move in the matter? There's money in it. What is supposed to be the Viola ledge has been struck in the Gallatin mine at Pyramid, and an additional force has been put on. The value of the ore already shipped from the Old Man mine at Fleming will not fall far short of \$100,000; and the out put shows no signs of diminution. Fleming continues to be the liveliest camp in the country. Peter Wagner is doing good work on his Atlantic No. 3 claim at Pinos Altos. The main shaft is now down 135 ft, and a whim has been erected for deeper working. The vein at the bottom of this shaft is three ft thick, the body having varied but little in the last 50 ft. The ore assays from \$80 to \$103 in gold, and from 10 to 27 ounces in silver. There are between 200 and 300 tons on the dump. Mr. Wagner has a good property, and has taken the preliminary steps to secure a patent.

Arctic Currents.

(CONTINUED FROM PAGE 434.)

June 7th, steaming from St. Lawrence Bay to St. Lawrence Island in calm weather, (time 20 hours) a current set the vessel thirty miles in an east, northeast direction.

July 2d, steaming from Behring strait to Marcens Bay, (time nineteen hours) the vessel was set to the northeast eighteen miles. There was no wind at the time, but for several days previously a fresh north, northwest gale had been blowing. In passing through the straits near the Diomed Islands at that time a strong current had been encountered which was the subject of remark on board, some estimating it as high as three knots per hour.

From 7 P. M., July 2d, to 4 A. M., July 3d, steaming from Marcens Bay towards St. Michaels, Norton sound, the current set the vessel east, northeast thirty miles.

At 4:30 P. M., July 12th, a short stop was made at Cape Prince of Wales. A northeast current necessitated frequent working of the engine to hold the vessel in position. Wind moderate and variable. July 30th while made fast to the shore ice at the east end of Herald Island, the current was measured with the chip and line and found to be to the northward one knot per hour. There was no apparent change in the velocity or direction of the current during the time the *Corwin* remained at the island, from 9:45, P. M., until 3 A. M. The ice was setting steadily northward during that time.

At Cape Wankarem, latitude 68°-5' longitude 176°-30',

A Tidal Current

Was observed with a rise and fall at that time of about two feet. The flood tide set along the coast to the northward. On the 4th of August while cruising in the strait south of Wrangel Island the meridian observations showed a west, northwest current of twelve miles, but as the position had not been determined by observation for two days previously, it would be impossible to locate the current definitely. However the main fact remains, the vessel had been set twelve miles in a direction away from Behring strait, the wind had been light and variable and could have influenced the current but little.

During the 4th and 5th of August the ship's position was determined by observations and a current found of one knot per hour, setting north, northwest, wind moderate from east to southeast.

On the 10th of August, while at anchor off the south coast of Wrangel Island, near the edge of the ice pack, the current was observed to be setting from one-quarter to one-half a knot, in a northwesterly direction.

August the 11th, when about eight miles off the southeast end of

Wrangel Island,

The current was measured with a chip and line, and found to be about three-quarters of a knot per hour, in a northeasterly direction (the direction of the coast line). During the night the ice continued to drift to the northward. The lead, in which the *Corwin* was at anchor, changed its position to the northward about eight miles. On the following morning, August 12th, while at anchor near the shore, off the east end of Wrangel Island, the current was observed to be setting north one and one-quarter knots per hour. The wind during the 11th and 12th was moderate from west to southwest.

August 13th, the vessel's position was determined by observation and the reckoning brought forward from the position of our landing place on Wrangel Island, showed a north, northeast current of one mile per hour, for the twenty-four hours. At midnight, August 16th, a short stop was made at Point Belcher, and the current was found to be setting to the northward along the coast about one mile per hour. The same current was observed a few hours later, when at anchor near Point Barrow. The wind during that day was light and variable.

August 17th, anchored at

Point Barrow,

Measured the velocity of the current, and found it to be one and three quarters miles per hour, following the direction of the land to the north and east. During our stay at Point Barrow the wind was light and principally from the eastward, so that it would have but little effect on the current.

August 18th, got underway from Point Barrow and steamed to the southward with a strong head current; wind fresh southwest, which, no doubt, accelerated the current.

At 7 A. M. the following day, at Point Belcher, found the current setting to the north-east along the land, but very much decreased in velocity; the wind was light southerly.

From meridian, August 19th, to meridian, August 20th, while steaming to the southward between Ice Cape and Point Hope, the vessel was set to the northward along the land thirty miles. From 5 P. M., August 20th, until meridian of the 21st, the current was found to have set twelve miles north by east, one-half east. From 4 A. M., August 22d, to meridian, August 24th, in Behring strait and sea between the Diomed Islands and Plover Bay, the current set seventy-five miles to the northward; the wind blowing a fresh gale from the south and southeast. Some days later in returning over this track, with a moderate wind, no current was encountered.

In September, the result of our observations in Kotzebue sound showed a tidal current with

a rise and fall of about three feet. The great Currents of the Arctic Ocean,

So far as known, may be briefly described as follows:

First—An easterly current through the cluster of islands lying to the northward of the American continent. This current is best shown by the drift of the English exploring vessel, the *Resolute*. After being abandoned by her people in Melville sound she drifted with the current through Barrow strait, Lancaster sound and Baffin's bay into Davis strait; a distance of about 1,200 miles.

Second—A southerly current between Grinnell land and the west coast of Greenland. This current has been often remarked by navigators, but is best shown by the drift of the *Polaris* while beset in Smith's sound, and also by the remarkable drift of a part of her crew on the ice floe through Smith's sound and Kennedy channel to the coast of Labrador.

Third—A southerly current between the east coast of Greenland and Spitzbergen. The strong southerly set met by Parry in those seas in his attempt to get north from Spitzbergen by means of boat and sled, and his heroic but unavailing efforts to overcome this obstacle by which Nature guarded that route to the pole, need not be recounted here.

Fourth—Still farther to the eastward, between Spitzbergen and the coast of Norway, a branch of the Atlantic Equatorial current, so much modified both in temperature and velocity as to be almost unrecognizable passes to the northward and loses itself in the icy regions.

Fifth—And last, the current through Behring strait and that part of the Arctic ocean lying to the northward. The existence of this current has been doubted by the Hon. Clements Markham, in a paper read before the Royal Geographical Society of London, and indeed by some of our own countrymen. They quote in support of their belief the incidental mention of the reports from the relief vessel *Rodgers*, which was burned while at anchor at St. Lawrence bay. The reports from her are said to show no northerly current in the vicinity of Wrangel Island, but a regular tidal current with a rise and fall of five feet. They quote, however, at the same time, the words of the New York *Herald* correspondent with the *Rodgers*; the latter says: "It was surprising to see the ice moving constantly to the westward along the shore." This is not only inconsistent with the theory that the *Rodgers* found no current other than a tidal one, but it agrees with the result of the *Corwin's* observations in that vicinity. From one-quarter to one half knot westerly current on the south side of Wrangel Island, and a northerly current along the east coast of the island. A glance at the chart will show the impossibility of a northerly current through Behring strait having any other than the direction indicated along the south and east coasts of that island, if unobstructed by ice. As already stated, however, all currents are subject to change in the vicinity of the ice pack.

One Theory Advanced

In relation to the Behring strait current is that it is caused by the rivers emptying into Behring sea and Norton sound. The effect of the rivers in Kotzebue sound was remarked by Capt. Beechey, R. N., who in speaking of a current encountered between Point Hope and Kotzebue sound, says: "It varied from one and a half to three miles per hour, and was strongest in shore; it was very constant, and the water was much fresher than the ordinary sea water." He adds, it is necessary here to give some further particulars of this current, in order that it may not be supposed that the whole body of water between the two continents was setting into the Polar sea at so considerable a rate. By sinking the patent log first five fathoms and then three fathoms, and allowing it to remain in the first instance six hours and in the latter twelve hours, it was clearly ascertained that there was no current at either of those depths; but at the distance of nine feet from the surface the motion of the water was nearly equal to that at the top. Hence we must conclude that the current was superficial and confined to a depth of between nine and twelve feet. By the freshness of the water alongside Captain Beechey believed that the current was occasioned by

The Many Rivers

which at this time of the year empty themselves into the sea at different parts of the coast, beginning at Schischmareff inlet. He further says, so far there is nothing extraordinary in the fact. But why this body of water should continually press to the northward in preference to taking any other direction, or gradually expending itself in the sea is a question of considerable interest.

The remark applies with equal force to such rivers in Kotzebue sound, as pass through Behring strait, while the decreased specific gravity of this river water due to its higher temperature and freedom from salt, would prevent its readily mingling with the surrounding salt water. The fact of its flowing northward through Behring strait, notwithstanding the course of the current is broken by shoals, sand bars, capes, islands, etc., is not so readily explained except upon the theory of the surrounding current having the same direction.

In proof of the existence of this current we have first the

Remarkable Drift of the "Jeannette."

This vessel entered the ice near where the observations of the *Rodgers* are said to have ap-

peared all existing theories in relation to Arctic currents; and notwithstanding the enormous friction of the ice, at points of contact, to be overcome, and in the face of adverse winds which many times set her back to the south and eastward. In twenty months, as a result of all currents, she had made 500 miles in a northwesterly direction. Unlike the drift of the *Resolute* through Barrow strait and Lancaster sound, or the *Polaris* party in Smith's sound and Baffin's bay, the *Jeannette* drifted in the open sea, where she was subject, in a much greater degree to the varying influence of the wind, and where the strength of the current would naturally be less than if confined within the narrow limits of a strait or sound. In view of these facts it is believed that this drift furnishes proof of the existence of a northerly current which has its origin south of Behring strait, in comparison with which all observations yet made sink into insignificance.

Then we have the

Formation of Shoals

On the north side of all points on the American continent, from Behring strait to Point Barrow. Beginning at Cape Prince of Wales we find that, although the water to the southward shoals gradually to the shore, the detached shoal lies entirely to the northward of the cape. At Point Hope we find the detached shoal with four and one-half fathoms of water on it entirely to the northward with twelve fathoms of water inside within two cables' length of the point. The same is true of Cape Lishourne, a shoal with five fathoms of water, lies wholly to the northward of the cape. The Blossom shoals off Ice Cape appear to be due to other causes than the current, possibly some peculiarity of the bottom. This, however, is a mere surmise, and is made upon the ground that they differ greatly from other shoals found along the coast, which are subject to nearly the same conditions of ice and current. Although lying to the northward of Ice Cape, they differ in the fact that instead of one, there are several of them, lying parallel with the shore and having deep water between them.

At Point Barrow the detached shoal lies entirely to the northward, although shoal water exists along the shore, to the southward.

The Drift of the Behring Sea Ice,

Through the strait into the Arctic ocean, each year, and the fact that the southern limit of the Arctic pack retreats to the northward with well closed edges, during the summer, until brought south again by the fall gales, cannot but be regarded as another evidence of the northerly direction of the current.

The fact that of all the whale ships lost north of Behring strait, but one has been found south of where wrecked; the discovery, near Herald Island, of part of a vessel burned south of Behring strait, must also be regarded as evidence pointing in the same direction. We have also the testimony of whalers, the only men who navigate these seas regularly, not one of whom, so far as I can learn, doubts the existence of this current. Then comes the testimony of the natives living on the shores of Behring strait, to the same effect. But in all this evidence, there is nothing inconsistent with a regular tidal current in Behring strait.

In a paper read before the Geographical Society of the Pacific soon after my return from the Arctic ocean in 1881, I stated my belief in a tidal current in Behring sea and the Arctic ocean, and also that a branch of the Kiro Siwa, or

Japanese Warm Stream

(so called), passes through Behring strait, hot, however, subject to the ever-varying conditions of wind and ice; and in applying this name to the origin of the current which, I believe, passes through Behring strait, I referred not to the small stream separated from the main body of the equatorial current by the Japan Islands, and which flows northward as a separate stream only so long as it is separated by these islands, but to the western edge of the great equatorial current which makes the circuit of the North Pacific, and to which the name of the smaller stream has been applied. The impossibility of this small stream maintaining a separate existence from the Japan Islands to Behring strait, with anything like a uniform velocity and temperature and clearly defined edges, must be plainly apparent when we consider the facts.

The Effects of Wind

Upon the surface currents of the ocean are too well understood to require discussion at this time. To the winds are due the equatorial currents of both oceans, while ocean currents night and would occur if not influenced by winds. In the constant efforts which are made by the sea to maintain its equilibrium in spite of disturbances due to difference of temperature and the consequent difference in evaporation, these currents would necessarily be slight and nearly in the direction of the meridian owing to the positions of the disturbing elements, heat and cold, and not at right angles to the meridian as is the case with the equatorial currents of both Atlantic and Pacific oceans. These are caused by the trade winds, and run in a westerly direction, until turned in the direction of the meridian by contact with the eastern coast of the great continents.

In the case of the Atlantic currents, the new direction is to the northward, owing to the direction of the coast line upon which it impinges, while the Pacific current is divided, one portion flowing to the southward. But it is the northern branch which is now under consideration, a small portion of which, I believe,

passes through Behring strait, but in a modified form, both as to velocity and temperature.

Referring again to the causes of the difference in the

Specific Gravity in Sea Water

In different parts of the ocean, the temperature and percentage of salt, we find that the former decreases and the latter increases it, and as in case of two strata of different density coming in contact, the stratum having the greatest specific gravity would, in obedience to the laws of gravitation, sink below the other, it will be seen that an equatorial current can exist as a surface current only so long as its temperature is sufficiently high to render it lighter than the adjoining stratum. As it comes in contact with the colder waters in its passage, its temperature becomes lower and it sinks below the waters of the higher latitudes, which, on account of decreased evaporation and the large amount of fresh water discharged into it from streams of melted snow and ice, contains much less salt, after which it may continue its course as a warm under current until neutralized by the surrounding water; or, as in the case of a shallow body of water, like Behring sea, the result of a contact between two currents of different temperatures must be the creation of a single current by the mingling of the two, whose direction will be that of the stronger of the originals, and whose velocity, temperature and specific gravity will be their mean.

A Branch of the "Kiro Siwa"

Extending to Behring strait would thus be very much modified in all respects, in fact, its temperature could be but little above the normal temperature for that latitude, consequently the comparatively low temperature of the waters of Behring strait is not inconsistent with that theory, as has been claimed, neither has anything yet been made known which in any way conflicts with the belief so long held by navigators in a northerly current through Behring strait, which has its origin in the equatorial current of the Pacific.

In my opinion the mistake lies in applying to this current the name of "Japanese warm stream." The name suggests an erroneous idea,

Death Valley Borax Mines.

The Eagle borax works are situated in Death valley, near Bennett's wells. The Inyo *Independent* says the plant consists of 320 acres of borate lands, situated about twenty-two miles south of the Coleman works, and ninety miles from Daggett station, on the P. I. branch of the S. P. R. R., hence all the freight goes that way. At the works the raw material is boiled in tanks twenty feet long, three feet wide and two deep, and is afterwards cooled and crystallized in twelve galvanized iron tanks. The production of refined borax so far amounted to twenty-two tons per month. Mesquite wood from the borders of the valley, and nut pine from the Panamint range furnish plenty of fuel; and good water abounds, surrounded by about twenty acres of meadow land. The first shipment of thirty-seven tons of crude material realized eight cents per pound, the article being of unusual purity, and, according to Prof. Price, about equal to the best refined article.—*San Bernardino Index*.

AN ADVERSE VIEW.—Wm. B. Owens writes to the *Sierra Tribune* from Harrisburg, Alaska, on date of May 1st and says: "There is no money in the place. Traders use leather checks to trade with. People are coming here on every ship by the hundreds, and a majority of them have no money to get away on. There is no chance here to work for wages, for there are no mines to work. A man cannot walk one mile on account of the underbrush and moss being so thick. The only way a man can get around is in a canoe. There is no gravel around here, and the quartz does not amount to much. There is some quartz on Douglas Island which prospected very rich on top, but gave out a couple of feet from the surface. Tell the citizens of Sierra county not to come to this country at present, for there is nothing here. Something might be developed in the interior after a while; but that will not be for some time yet, as it costs too much now to get out through the country. It costs ten cents a pound to get stuff over the portage after it leaves the canoes. It is packed on the backs of Indians. The Yukon river, which is about two thousand miles long, is the place I speak of when I say the interior. No one knows anything about the river so far as gold is concerned. Harrisburg is on the lower edge of Alaska. The weather here is fine. We have a little rain daily. The days' length at this writing is about twenty hours."

THE MALAYAN CANAL.—The Survey Commission for the cutting of the Isthmus of Kra has returned to France. It has been six months on the Malay Peninsula. Lieutenant Belton, in charge of the survey, declares that the cutting of a maritime canal on the level through the isthmus will present insignificant obstacles. The isthmus is an uninterrupted forest of the most valuable timber. The lower stratum of the ground is granitic; the upper almost everywhere is soft sandstone. The length of the canal is 111 kilometers, fifty of which have to be cut. For the rest of the distance the river will be utilized.

THE San Francisco and Pacific Stock Exchange have resolved to adjourn from the close of business on Saturday, June 30th, to Thursday morning, July 5th—over the Fourth of July.

THE ENGINEER.

Progressive Designs Upon the Holy Land.

China and Japan, after the lapse of centuries, were at last compelled to open their ports to foreign trade and to adopt many of the improvements of higher civilizations. And now it is proposed that the Holy Land shall be aroused from its lethargy to experience a thrill of the progress which has lifted the surrounding nations into commercial prosperity and political greatness. An English company, with the Duke of Marlborough at its head, has been formed to make the preliminary surveys to find out whether it will be practicable to carry out several suggested enterprises. The first contemplates a canal twenty-five miles in length from Haifa, on the bay of Acre, through the plain of Asdrachon to the valley of the Jordan, to be 200 feet wide, which would conduct the waters of the Mediterranean into the heart of Palestine. It is further proposed to build a canal twenty miles in length from the head of the gulf of Akabah to the Dead sea. The *London Railway News* says: "If these plans are carried out it is expected that an inland sea, about 200 miles long, varying in width from three to ten miles, and deep enough to float vessels of the largest size, would extend from the Mediterranean to the Red sea." Supposing it possible to overcome all the engineering difficulties in the prosecution of these grand works the consent of the Porte will be necessary before they are undertaken; and it is feared that certain European Powers would offer objection to any privileges of an exclusive character being granted to England. The *London Times* refers to the proposed enterprise as follows:

It is possible the new enterprise may be proved to the satisfaction of many devout men and women to be the fulfilment of the prophecy of Ezekiel, to the effect that there is to be a broad sea in the desert, and that "the fishes shall stand upon it from Engedi even unto Engedi."

A WIRE TRAMWAY ROAD FOR PASSENGERS.—Some enterprising men of Colorado have conceived the idea of building an "elevated" tramway to the summit of Pike's Peak for the transportation of those who desire to experience the solitude of that high. The altitude of the mountain above the sea is 14,200 feet, and the length of the road in making the ascent will be about nine miles. It is proposed to build the line in three divisions, each operated by a different motive power. The tramway is to be an endless wire cable carried on substantial supports at a height of about twenty-four feet above the ground. Attached to the cable at intervals of about 100 feet there are to be large arm chairs, each capable of holding two persons. The first division will be from the iron springs at Manitou, and the cable will be moved by a steam engine at the lower terminus. The cable of the second division, higher up the mountain, will be moved by power from a turbine wheel, driven by the water from one of the cascades on the mountain. On the third and upper division the cable will be operated by a steam engine located at the signal station on the summit. Platforms are to be constructed at the ends of each division, so that passengers may safely and quickly change cars. It is expected to complete the line by August 1st. The proposed fare, it is said, will be \$5 for the round trip. The plan seems feasible enough so far as the construction of the line is concerned, but the working of the boiler and engine at that altitude is a matter of experiment, and as all the fuel will have to be transported over the line for the summit engine, it remains to be seen how much surplus steam there will be on hand after drawing up the coal.

WATER GAS FOR STEAMSHIPS.—A test is about to be made in Great Britain in connection with the use of water-gas as a fuel for steamships. It is reported that the Mauritius Steamship Line has built a steamship called the *Heron*, of 1000 tons burden and provided it with the necessary apparatus for the purpose in question. The *Heron* is to ply between London and the islands of Mauritius and Madagascar, and it was expected that she would start on her trial trip about the middle of this month. She has been fitted out with six furnaces, and great expectations are entertained as to her saving in fuel. It is also rumored that another English steamship company has placed sufficient confidence in the project to begin the construction of a vessel without coal bunkers.

MARKET STREET CABLE ROAD.—On the 15th inst. the cable on the Valencia street extension of the Market street railroad was laid. It took eighteen horses to pull the cable through to the terminus beyond Twenty-sixth street, and to haul the great wire rope around the drum there and back to the engine house at Valencia and Market streets it required twenty-two horses. The cable is four and one-quarter miles long. The first car for this cable road left the Central Pacific railroad shop at Sacramento on Thursday of last week. Thirty-six have been ordered, a dummy and coach in one piece, and two four wheeled trucks instead of the usual four-wheels with dead axles.

USEFUL INFORMATION.

HOW TO KEEP CUT FLOWERS.—A reporter found his way into a florist's and feasted his eyes and nose on the beautiful buds that lay in bouquets there. "How long will this clove pink last?" he inquired. "Oh, with care, a week or ten days. A solid rosebud will last about the same time. There's a good deal in knowing how to keep flowers fresh." "Do you use any preparations—any salt in the water, or ammonia, or the like?" "Not at all. That's all nonsense. All that is necessary to keep flowers fresh is to keep them moist and cool. If people, instead of dipping flowers in water or putting them in a vase with water, would simply wrap them up in a wet newspaper, they would find that they would keep far fresher over night. A wet towel or napkin would be too heavy and crush the blooms too much, and besides, it would allow the moisture to evaporate too easily." *Cleveland, Ohio, Herald.* On the above, the *Scientific American* says: Flowers can be preserved in their natural form and color. Insert the stems in water, in which twenty-five grains ammonium chloride (sal ammoniac) have been dissolved. Flowers can be preserved in this way for fifteen to thirty days. To preserve them permanently for several months, dip them into perfectly limpid gum water, and then allow them to drain. The gum forms a complete coating on the stems and petals, and preserves their shape and color long after they have become dry.

A PICTURE IN THE HEART OF AN OAK.—A correspondent of the *Waterbury, (Conn.) American*, writing from Watertown, says that Mr. Benjamin Marvin, of that town, in splitting a log of black oak, observed a picture on the smooth grain in the heart of the tree. It is a landscape, or rather a clump of trees, with trunk and branches and twigs as clearly defined as though drawn with ink or photographed by the sun's rays. The trees form a picture about four inches square, showing like the open leaf of a book, and the same on the opposite page. Mr. Marvin says it is a pretty good portrait of the clump of trees which he felled, the picture appearing in the heart of the largest one. Such pictures are sometimes said to be a result of lightning flashes, but they are more commonly the result of the arborescent crystallization of manganese. They are quite common on the cleavage faces of different rocks. The so-called pictured rocks are produced in a similar manner.

A NEW METHOD OF MANUFACTURING BELTS or bands for machinery, which comes from Paris, is applicable to rubber, woven tissues of gutta-percha, and consists in making the belt in longitudinal ribs or grooves, the main object of which is to increase the capacity of the belt on the same cross section, say twelve inches, by the extra strength put in the same space, and also to prevent so much stretching and variation. Another modification of the same invention, is grooving one side of the belt the same as saw teeth, then putting these two pieces together, leaving a plain bearing surface for contact besides, thus making a double belt, which is less liable to stretch or to warp. Especial machinery is built for the purpose, and the claim for it is that better contact is given. The pores are closed during this grooving process, the belts having a higher resisting power, and do not twist on the pulleys. The grooves may be regular, irregular, spiral, or crossed.

AN ELASTIC LACQUER.—A lacquer, said to be of great elasticity, perfectly supple and not liable to peel off, is made in the following manner: About 120 pounds of oil varnish is heated in one vessel, and 33 pounds of quicklime is put into 22 pounds of water in another. As soon as the lime causes an effervescence, 55 pounds of melted Indian rubber are added. This mixture is stirred and then poured into the vessel of hot varnish. The whole is then stirred so as to be thoroughly mixed, then strained and allowed to cool, when it has the appearance of lead. When required for use, it is thinned with the necessary quantity of varnish and applied with a brush, hot or cold, preferably the former. This lacquer is useful for wood or iron or for walls; it will also render waterproof, cloth, paper, etc.

JOINING RUBBER BELTS.—There are a great many plans for joining the ends of rubber belts. Some use rivets, others hooks, but lacing is considered best. The manner of lacing is of considerable importance, as the strength of the belt is only equal to the strength of its weakest part, hence the most economical manner of joining the ends is that one which will make the strength of the joint equal to the average strength of the belt. India rubber is a good substance for belts that are exposed to the weather, as it does not absorb moisture. Belts should not be subjected to a strain of over three pounds to the square inch of section, and beyond a certain point tightness has but little effect.

HORN MAY BE WELDED or joined by heating the edges until they are quite soft and pressing them together until they are cold. It may be softened, after sawing it into plates or sheets, by exposing it to powerful pressure between hot iron plates. Before pressing, the pitch must be removed, and the horn softened, first by soaking for some days and then boiling in water.

GREASY COLOR.—The painter is frequently annoyed by having his paint or varnish crawl, or draw up, leaving bare spots, when applying it over a painted surface. The cause is what is known as "greasy color" that is, if the paint was not mixed with oil it is a greasy pigment, such as lamp-black, but the most common trouble is too much oil. To overcome the difficulty wash the surface, or simply rub a damp sponge over it; or, if it be only a small spot that appears "greasy," blow the breath upon it, and the crawling will be overcome. *Painter's May Time.*

PRESSURE WILL NOT PREVENT FREEZING.—Water will freeze, however closely confined, if the proper temperature is present. If powder or dynamite is confined in a chamber, that is strong enough to prevent bursting, it will not prevent the chemical combination, when brought to the proper condition for explosion, whether by heat or otherwise. The pressure will last until reduced by cooling, new combinations, or waste. These experiments have been made by firing a confined charge and allowing it to waste through a small vent.

A PERSON AGED AT EIGHTEEN.—There is in Schuylers county, Mo., a young old man, who, without apparent cause, living plainly on a farm, has in eighteen years passed through the physical changes of fourscore. At the age of six he had all the development of strength and muscle usually in a lad of fifteen. At twelve his beard was grown and gray hairs appeared. Now, at eighteen, he is as decrepit as any old man of eighty, and seems tottering on the verge of the grave.

M. POMPIER, a French aeronaut, has made two ascents with elongated balloons, carrying four people. Both were successful. In his second he obtained a movement of the balloon in the required direction by the action of his rudder independent of the wind, which appears to be the first time any aeronaut has done so.

PREPARING SMOKED MEAT.—When meat is exposed directly to a thick smoke of a fire of any kind, the lamp black will accumulate on it, giving it an unsightly and unsavory appearance. Put the meat in sacks made of thin cloth, which will admit the creosote and keep off the coarse smoke.

The *Journal de Pharmacie* says that a nuclide composed as follows will unite wood, porcelain, or glass: Eight and a half ounces of gum arabic in strong solution, twenty grains of solution of alumina dissolved in two-thirds of an ounce of water.

GOOD HEALTH.

Natural Cure for Consumption.

We have before us a valuable little treatise, the title page of which reads as follows: "Natural Cure of Consumption, Constipation, Bright's Disease, Neuralgia, Rheumatism, Colds, Fevers, etc.—The Origin, Prevention, and Removal of Disease. A Manual of Hygiene for well and sick. By C. E. Page, etc., author of 'How to Feed the Baby,' etc. Two hundred and seventy-eight pages, 12mo., extra cloth. Price \$1.00. New York: Fowler & Wells, Publishers, 753 Broadway."

From a careful review of this work, it would seem that we have, at last, a health book, written by one who has devoted his life to the study of the prevention, as well as cure, of sickness, through a rational interpretation of natural laws. "Is consumption curable?" is a question which—outside of nostrum venders and charlatans, who have no scruples against lying for gain—has long since been answered in the negative. There is a conviction to this effect, in the minds of the people. The local doctor, of whatever school or skill, is no more expected to cure consumption, than to extend the average age of man to a round century. Indeed, if the patient recovers, it is declared throughout the community that the disease was not consumption after all, for, "if it had been, he would never have recovered!" While endorsing this position as regards patients who shut themselves up at home and submit to medication, Dr. Page shows, by reference to the records of the dissecting-room, that partially consumed lungs do often heal, and that many persons who have never, perhaps suspected the presence of the disease, have lived for many years with less than an entire pair of lungs. Even after one-half of a lung has been destroyed, a perfect cicatrization of the tuberculous ulcers has taken place, and there has continued to be performed all the essential functions of the sound organ. "But," says our author, quoting Dr. Oswald, "in ninety-nine out of a hundred cases it will be found that the first improvement followed (not upon a change of 'doctors,' nor the swallowing of an irregular nostrum, but) upon a change from a sedentary to an out-door and active mode of life." He affirms the position that, given anything like natural conditions, such as it is the aim of this book to prescribe, "pulmonary consumption in its earliest stages is, perhaps, the most curable of all chronic diseases." A most remarkable case of self-cure, that of a young and determined girl, whose disease had passed to the "last stage," is given, and vouched for as an actual fact. The work is designed to illustrate the "food and fresh air cure" for

"dyspeptic starvation," which is Dr. Page's definition of the disease under consideration.

With relation to the dreaded Bright's disease, while agreeing with the most eminent physicians of all schools that this is a disease resulting from excessive or ill-conditioned diet, still, unlike almost all practitioners, Dr. Page holds that this, too, is a disorder which is readily amenable to "natural treatment." The consideration of the other diseases named is somewhat unique in character, and the author maintains that a strictly natural regimen is not only preventive, but curative of all disorders, so long as a restoration to health is possible, and this, too, at stages subsequent to what are, in general practice, held to be incurable. The book relates mainly to a disease whose treatment, judged by the mortality reports, has been radically wrong; and, as a whole, will repay a careful perusal, even by those who feel obliged to dissent from some of its conclusions. It is designed not only for popular reading, but as a text-book for physicians of all schools, the most intelligent of whom are coming more and more to realize the importance of hygiene as an aid to, if not as the principal treatment of, all disorders.

BATHING ABUSED.—Doctor Sargent, medical director of the Christian Union gymnasium, Boston, astonished a lecture audience, by the assertion that there can be abuse in bathing. Our cities are full, he said, of thoughtless persons, who pride themselves upon being superior creatures, because they indulge in the luxury of a full bath daily, with a frequent Turkish or Russian ablution as an extra—a kind of bath which the doctor thinks should only be taken under advice for disease. He explains that free perspiration and the wearing of heavy flannels, promote the functions of the skin, so that only an amount of bathing essential to cleanliness, is needed to maintain health. Warm baths are the substitutes which luxury has devised to do the work of exercise and make up for the deficiencies of artificial life. Twice a week is often enough to take them, according to the lecturer, as their too frequent use is debilitating. The tonic effect of a cool sponge bath in the morning, would not willingly be given up by those who know the delightful after-glow and the protection which the habit affords against colds; but here again a discriminating science, lacking up common sense, steps in and says: "No cold bath, unless they are agreeable and you are, in point of health and vigor, fully up to it." The intelligent person who learns to "know his frame," and to observe the effect of diet, bath and exercise, can usually order his life better than anybody can direct it for him.

HEALTHFUL EXERCISE.—Walking, of itself, says Dr. Sargent, of Harvard College, is of no value as an exercise, but a spirited walk is one of the finest of all exercises. If a man enters heartily into this exercise he will be benefited by it. Horseback riding is an excellent exercise for circulation, as very little of the nervous energy is expended. For a person who uses the mind excessively, however, this form of exercise is not good, as it produces nervousness. Swimming is, without exception, one of the finest of all physical exercises. It develops especially the lower portion of the chest, the legs and arms. Running, at a regular and fixed pace; boxing, to teach one to keep the temper under adverse circumstances; rowing and canoeing, to strengthen the upper part of the thorax and chest, are useful. The benefit to be derived from regular practice in a gymnasium, by which the mind and nerve-centers are so trained that they have a certain amount of control over the body, so that while the muscles may give out, this mental power, when once obtained by physical training, will never be lost, is of the greatest account.

ACONITE IN DYSENTERY.—The *New York Medical Journal* publishes an account of the treatment of 150 cases of acute dysentery by a Dr. Owen, who employed only a very weak solution of aconite, of which he administered about one drop an hour. This treatment was substituted for the regulation treatment with ipecac. The doctor commends the treatment very highly, and says that patients like it very much better than the nauseating doses of ipecac. We have no doubt that Dr. Owen's method is an improvement over the old one, but we have successfully treated fully as large a number of cases without either aconite or ipecac, employing chiefly the hot enema, with sufficient satisfaction to the patients to lead them to declare that they would afterward employ no other treatment in the event of a similar attack.

NITRATE OF SILVER AS A MEDICINE.—When nitrate of silver is used as a medicine for a length of time, the skin becomes of a peculiar bluish or slate color. Many may remember the familiar face of the blue man who formerly lived in this city, and whose face had assumed this singular hue. There is also a "blue man of Missouri" whose skin is discolored in the same manner and from the same cause. When about 15 he took five drops of a solution of nitrate of silver, containing 20 grains to the ounce, and continued this for five or six months. At the end of that time he observed that his face and hands were becoming dark. This color has become permanent, and hence his sobriquet. Nitrate of silver is sometimes used as a remedy in epilepsy.

Saturday Morning, June 23, 1883.

TABLE OF CONTENTS.

EDITORIALS.—Prospecting in Alaska; Surface Mines at Harrisburg, Alaska, 442. Limiting the Sea Otter; The Signing of the Declaration of Independence, 447. The Peerless Traction Engine; A Submarine Monitor; An Early Celebration; The Broken Dam, 448. Beach Diggings; Galvanic Treatment of Silver and Copper Ores; Mining Expedition to Alaska; The Outlook, 438. Passing Events; Close of the Volume; Our National Day; Map of Alaska; Mining Machinery; Immigration; Alaska Scenes, 440.

ILLUSTRATIONS.—Working Beach Diggings in New Zealand; Becker Glasses for Treating Copper and Silver Ores, 443. Scenes in Alaska—Harbors and Rivers of the Northwest Coast of Alaska, 441. The Signing of the Declaration of Independence; Sea Otter Hunting on the Pacific—The Alaska Islander's Canoe or Biadarka, 447. Herald Island in the Arctic; The Cow in a Nip off Cape Romanoff, 443. The Peerless Traction Engine or Road Locomotive, 448.

CORRESPONDENCE.—English Investments in Pacific Coast Mines, No. 6, 434.

MECHANICAL PROGRESS.—Damascus Steel; Why Iron Chills; Phosphorized Nickel; Metallization of Timber; Hollow Brick Walls, 435.

SCIENTIFIC PROGRESS.—Labor and Food; The Value of Metals; Philosophy of Quieting the Waves with Oil; Nature in Siberia; Observations on Sound; Permanent Lamp Attachment; Iron and Steel Magnetized by Breaking, 435.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends and Bullion Shipments, 436.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon and Utah, 436-7.

THE ENGINEER.—Progressive Designs Upon the Holy Land; A Wire Tramway Road for Passengers; Water Gas for Steamships; Market Street Cable Road, 439.

USEFUL INFORMATION.—How to Keep Cut Flowers; A Picture in the Heart of an Oak; An Elastic Lacquer; Joining Rubber Belts; Greasy Color; Pressure Will not Prevent Freezing; A Person Aged at Eighteen; Preparing Smoked Meat, 439.

GOOD HEALTH.—Natural Cure for Consumption; Bathing Abused; Healthful Exercise; Aconite in Dysentery; Nitrate of Silver as a Medicine, 439.

NEWS IN BRIEF.—On page 452 and other pages.

MISCELLANEOUS.—Arctic Currents, 434. Death Valley Borax Mines, 438. Alaska Mines; Scenery of the Northwestern Archipelago, 442. Change in Railway Trains; Note for Millmen, 447. Alaska, 444. To Yulter City, Maricopa County, A. T., 443. Alaska Bears, 443.

BUSINESS ANNOUNCEMENTS.

U. S. Submarine Monitor Co.—W. H. Milliken, S. F. Dividend Notice—San Francisco Savings Union. Dividend Notice—German Savings and Loan Society. Practical Metallurgist—G. H. Aaron, Pinal, Arizona.

Passing Events.

This week we devote our space largely to consideration of Alaskan affairs, and have obtained a great deal of information about this region which will be useful to miners and prospectors.

The approaching national holiday has already occasioned the usual temporary business lull, many taking the opportunity to have a short vacation. The customary festivities will take place in this and other cities on the coast.

It is noticeable that there are a number of custom mills and reduction works going up in various camps, where miners may have ore worked. Establishments are being fitted up, also, where ores may be sold. The increase of such facilities argues well for the future of mining on the coast.

Several new strikes are recorded in our "Mining Summary." The beginning of work with nickel ores, elsewhere alluded to, is an important thing. No doubt the starting up of a few mines will encourage prospectors to search for this valuable metal. There are doubtless plenty of other deposits than those mentioned.

Close of the Volume.

This number is the last one of Vol. XLVI of the MINING AND SCIENTIFIC PRESS. The voluminous index on the last page shows what a range of subjects has been treated during the past six months, and how great a variety of reading matter has been given. We have kept track of all new discoveries in science and mechanics, as well as in mining and metallurgy. The mining community has been able by our columns to keep pace with all improvements, by seeing what was being done in their branch in all parts of the world.

The MINING AND SCIENTIFIC PRESS is the oldest mining paper on the coast, and its experience in the field has enabled it to present such material as will be of use to the prospectors, miners, metallurgists and mining engineers in their business. We have taken trouble to describe in detail all new processes, machines, etc., that have come to the front. All the current news is given weekly in a condensed form so that people may keep posted as to what is going on in various districts. The newly patented inventions worthy of note have been described intelligently, and close watch kept of the decisions of the courts and departments affecting the mining interests.

We have published several double editions, and propose issuing others from time to time, devoting considerable space to certain localities. The PRESS is one of the factors of mining progress on this coast, and is a journal mining communities cannot well dispense with. While its advertising patronage and subscription lists are now well advanced, the better support we have the better journal we can issue. We have several improvements now in view, and need the co-operation of all interested in the mining industry. It is well to add that the beginning of a volume is a good time to send in names for subscription and to renew. Those who know the merits of the PRESS will oblige the editors and publishers by calling the attention of others to the paper.

Our National Day.

It is one of the noblest endowments of our nature, that while standing on this fleeting point of time we can look both ways. By memory and history we may in some degree recall the past, and by hope and imagination anticipate the future. We are now concerned with only one great event in the past. Next Wednesday is the natal day of our Republic. There are days that come to us all fraught with such special remembrance, that it seems to be a duty to put ourselves into an attitude to breathe what is healthful in the passing air. We are such slaves of association that we can most easily think and feel the stir and thrill of great ideas in our country's history, upon the day that comes most fragrant with national memories. And yet it is not possible in a brief article to lift the veil of Time and tell the old story, how two millions of people moved by one patriotic impulse, forsook the plow, shop, counter, and home, to follow the fortunes of their new-made flag over many a bloody field, till victory crowned their efforts at Yorktown. But we shall find the spirit that animated them embodied in the events that immediately led to the declaration of independence. Let us watch the process of a nation's birth!

The movement for independence was not any sudden explosion of heated passion, nor was it the work of any one man or set of men. For months it had been talked over as a "consummation devoutly to be wished," by the mechanic in his shop, the fisherman along the northern coast, the planter in the sunny south, and the pioneers and hunters of the west. It had been warily discussed in town meetings, social parties, in the pulpit, newspapers, by the Committee of Safety, and the Provincial Legislatures. The members of the Colonial Congress were no company of reckless adventurers, who had everything to expect and nothing to lose by a revolution. They were slow, cautious men, who long hesitated and were silently borne on the current of events. June 7, 1776, Richard Henry Lee, in the name and by the special authority of Virginia, proposed this resolution: "That the United Colonies are and of right ought to be free and independent States; that they are absolved from all allegiance to the British crown, and that all political connection between them and the State of Great Britain is and ought to be dissolved." This was the first

step. It was intended as a feeler. The lighting was in the hearts of the people and only needed an electric touch to cause it to flash upon the world. That touch had been given. But how timidly the great actors in this mighty drama came upon the stage. The resolution was seconded by John Adams. A long and warm debate followed. Many members were afraid to take the decisive step. They still hoped that the eloquence of Chatham, and the influence of Rockingham might effect an honorable reconciliation. It was finally agreed to adjourn the discussion of the question until the first day of July. The time arrived to consider the resolution. Fifty-four members were in their places. The outlook was ominous. The business of the day began by reading a letter from General Washington, who returned the whole number of men under his command who were fit for duty as seven thousand, seven hundred and fifty-four. Many of these were volunteers for a year, whose time of service was nearly out; all needed money, clothing, and ammunition, and Congress had no credit, and no power to levy a tax. Sir Henry Clinton had just arrived before Charleston with a line of battle-ships, and the safety of the place was in doubt. New York was threatened by Lord Howe, with a formidable armament that had already arrived at Sandy Hook. General Montgomery had panted out his brave soul under the walls of Quebec, and the little army that had invaded Canada with fair hope of success, was on the retreat, badly shattered by disaster and disease. The Indians on the frontier were already on the war-path. As yet no foreign power had sent a word of sympathy that could kindle a ray of hope in the bosom of the most sanguine. Such was the state of affairs on the morning of the first of July, 1776. Is it any wonder when the order of the day was announced that for a few moments there was a profound silence. Who could foresee the future? There might be defeat, confiscation, and the scaffold lurking in the silent coming months. John Adams broke the solemn stillness by a speech, which tradition says was impressive, impetuous, and powerful, and like a mighty torrent, swept away every objection; and on the evening of the second day the resolution passed, only one dissenting colony, New York, not yet able to concur. The Rubicon was crossed. The old thirteen British Colonies stepped forth among the nations of the earth free and independent States. A committee was immediately appointed to prepare a formal statement of the reasons of the separation. Mr. Jefferson drew up the paper, and showed it to Adams and Franklin, who made only a few verbal corrections, and Congress entered upon the consideration of the document. For two days its statement of principles and reasons were sharply analyzed, and every word critically scanned. On the Fourth of July, 1776, it received the approval of Congress, and copies were ordered to be sent to each State, and that it be read at the head of the army, and it was everywhere received with an unbounded, spontaneous enthusiasm by the people. As long as this day is cherished in patriotic memory, and the sentiments of that memorable document burn and glow in the hearts of the people throughout the land, the stability of the Union is assured, "One as the Sea but multitudinous as the waves."

Map of Alaska.

The large map of Alaska which we publish in this number of the MINING AND SCIENTIFIC PRESS, was drawn for us by Mr. W. D. Patterson, C. E., from latest available data. It takes in those portions of the extensive region which are of interest to the miner and prospector. By it may be seen the main water courses of the territory, by means of which inter-communication is carried on. Of course, on such a scale, it would be impossible to delineate the smaller streams. Yet there are thousands of them in every direction, as might be expected from the character of the country.

The coast line of Alaska is indented with harbors and rivers, from one end to the other. "Hundred harbored Maine" does not possess a more ragged coast line. Smaller courses run to the waters' edge everywhere, making it difficult to penetrate the country much back of the river lines.

Our map, which we engraved especially for this edition of the PRESS, will be useful to all interested in Alaska. Where possible, we have indicated the geological formation; but the region has been only slightly prospected, and complete data are wanting.

Mining Machinery.

Mr. Edward A. Rix has recently leased the whole of the large building on Fremont near Market street, formerly occupied by Jonathan Kettridge, and has remodeled it and made extensive improvements, to adapt it to his growing business. It is now arranged to carry on a general machine business. Mr. Rix also carries on the business of the late Mr. Kettridge, making iron shutters, doors, etc. The shop is particularly well lighted, the proprietor having sacrificed considerable floor space in order to have good light on the lower floor. No shop in town is better arranged in this respect. The forging and machine shop has all the necessary tools, lathes, planers, etc.

Mr. Rix makes a specialty of small steam engines for general work. He makes one with boiler and all, for small work. He is also agent for the well known Knight water-wheel, which is in use in many parts of this coast. Aside from the general mining machinery, in which Mr. Rix deals, a specialty is made of the Rix hoist, a very effective type of machine for its purpose, strong, durable, and of a type which experience has recommended. Quite a large stock of wire rope is also being taken in. This rope is made in St. Louis and Mr. Rix has now an agency for its sale. The Heald & Morris horizontal engine is also kept in stock.

The principal business carried on, however, is that connected with the National rock drills and compressors. These drills are all over the coast. There are 30 of them running on the Oregon and California company's road. There are 12 or 15 in the Idaho company's mine, Nevada county, and also five in the Conpromise mine, Conterville; two in the Sierra Buttes, etc. A mine in Montana has just ordered 16 of these drills, which we are informed is the largest single order of the kind ever given on this coast. There are a number of small mines here using one or two of these well-known drills, among them may be mentioned the Murchie, Springfield, Pacific, Empire, etc. Mr. Rix has furnished drills and compressors for all of the railroad plants on the coast.

The new front on the old building has greatly improved it. The floors have been fixed up and the general design remodeled. There is an incline from the basement to the sidewalk, divided with a track for a car, a wire rope with power being used for hauling up heavy material from the lower shops. Mr. Rix did not have sufficient room at his old place of business but now has commodious premises well adapted for a growing business.

Immigration.

In compliance with an invitation from the Sacramento Board of Trade, Arthur R. Briggs, president of the Immigration Association, and C. H. Street, secretary, appeared before the board last Friday evening in Sacramento, with a view of interesting the merchants of that city in a plan to bring the northern and eastern portions of the State more prominently before the people of the Eastern States and Europe. It was proposed by Mr. Briggs that the Sacramento merchants raise the sum of \$3,000 for the purpose of platting the government lands in those sections of the State tributary to Sacramento; and also for taking the field notes from the books of the office of the Surveyor-General, and to make a personal examination of the lands, the work to be published in pamphlet form for distribution. Mr. Street exhibited the plats of Butte, Lassen, Shasta and Placer counties, as made up in the office of the association, which showed what lands were open for settlement, available for agricultural purposes etc. It was estimated that 25,000 families could be located in the fourteen counties tributary to Sacramento on available government land, besides which there is a large area of timber, mining and swamp lands. The Sacramento merchants favored the proposition, and those present subscribed the sum of \$900 for the purpose, and appointed a committee to canvass for the sum required. It was proposed that subscription be made at a basis of a certain sum for twelve months, the subscriptions to be made in quarterly installments to the Board of Trade, and by them paid over to the Immigration Association.

Alaska Scenes.

On page 481 of this number of the PRESS are several fine views of Alaska scenery. Figure 1 is a view of the town of Sitka. Figure 2, shows Sitka Harbor, looking seawards with its numerous wooded islands and protected anchorage. Fig. 3 is one of the legendary carvings found at Fort Simpson and other localities. These images are not worshipped, but are rather historical or legendary. Fig. 4 is an Alaskan river scene, the houses and huts of the villages clustering along the bank. Fig. 5 illustrates Wrangel. All these localities are more fully referred to in other parts of this issue.

SCENES IN ALASKA HARBORS AND RIVERS OF THE NORTHWEST COAST OF AMERICA.

Prospecting in Alaska.

From a conversation we recently had with an Alaska miner, who has spent several seasons there, we were given the impression that the country is rather a bad one to prospect in. Strangers not used to the Indians have the most trouble. The Indians know those persons who have passed several years there. The old hands have, therefore, the best chances. The natives are more liable to commit depredations on strangers. The moss, bogs and timber are great hindrances to the prospector's work. Canoes and boats have to be used for transportation. After a mining camp is struck it is all right, but hunting up the camps is hard work. Rivers, mountains, timber, marshes, etc., are serious obstacles. When a lot band together as did the men who went up the Yukon last year, it is all right, for they can take a small steamboat.

The ordinary prospector cannot do this, but must carry provisions long distances and otherwise rough it pretty hard.

The dense mass of moss which covers so much of the ground is the worst obstacle, however. Men can make but few miles a day with such walking. At any time they may slip through into boggy, wet ground. To do any prospecting, they must remove this covering of moss. On the coast it is not so cold, but in the interior in winter the cold is extreme.

Harrisburg is 180 miles from Sitka, and is the same distance from Wrangel that Sitka is. Wrangel is an unimportant place that the Cassiar mines built up. For three or four years there was good leads, but now there is little doing.

Some few men stay at Harrisburg all winter, and there is some little work done on the ledge or the island. With its very short days, and its cold, little can be done in the winter; it takes about all the available time to gather wood to keep warm with.

None of the men ground-sluice. Little is being done with quartz on the main land. Four years ago there was quite a rush to Alaska, but last year few men went. Men have been pushing into the interior for the last three years. They go up the Chilcat river as far as they can, and then pack across the range and get some gold; they even go over into British Columbia; They try to get on the continuation of the Cassiar gold belt.

About Harrisburg there is nothing in the creeks at all; and this is the case elsewhere. The auriferous gravel is on the hills, but there is no "wash" down below. The gravel has evidently been formed by glacial action and the gold has not been washed down into the hollows and ravines, as it has in this country. In ordinary gold-bearing regions men prospect the creeks first, here they do not; the experience about Harrisburg taught the miners this.

The country is a bad one for a man to get "broke" in, because there is no chance for him to get days-work, and distances are great with few settlements. Men without means should never think of trying to do anything mining or prospecting in Alaska.

Surface Mines at Harrisburg, Alaska.

In conversation with a miner, who owns claims at Harrisburg, we were told that the claims are in high banks or benches, and the gravel is from three to twenty feet in thickness. The material is a sort of decomposed stuff—a mixture of broken quartz and other debris. Sometimes a reef of quartz will be met with in the gravel bed.

Water is plenty, and is brought to the gravel beds in ditches from the creeks. There is no company furnishing water, the miners bringing it themselves to their claims. The season lasts from five to six months, but varies considerably. The miners at Harrisburg take up 200 feet frontage on the hill ground and 1,000 feet running back. Most of the mines are on the mainland, but there are some on the islands. There are two companies mining on Douglas island.

All the region close around has been taken up. Some little prospecting outside has been done, but it has not paid. The mines are not in a regular gold belt; it does not seem to be a regular wash. The belt cannot be traced at all. Wherever stringers of quartz are found, placer ground is met with around it. The quartz and placer ground have to be recorded separately.

The creeks do not yield gold. The "basin" is two or three miles above Harrisburg, and diggings are around this basin. Hydraulic nozzles are used there, the same as we have in California. The character of the gravel is different, for it is broken up by glaciers, and not in the shape it is as with us, where water has acted upon it.

Alaska Mines.

Placers and Quartz near Harrisburg.

(From our Alaska correspondent Geo. E. PULZ.)

In all the reports and letters written about our Alaska country but very little truth or correctness has been shown. But I feel it my duty to say something about our country to the public from my stand point. Since the discoveries of the Harris mining district two years ago last fall, Harrisburg has had but very little attraction for outsiders; yet we must not be thrown entirely in the shade. But very little having been done with our mines but light prospecting, we are still rather obscure, although our little settlement has done very well for itself. It has started out on its own merits and I expect will have to keep on to work up on its own merits. Being so far away and cut off from any other country, it is no wonder that we have not come before the notice of the public more than we have. The placer mines about whose uncertain prospects I wrote you two years ago, not being an expert placer miner myself, have far outreached my estimates. With a small lot of 100 miners in 1881 the camp produced from reliable authorities \$150,000 in gold dust, for which amount I can also vouch, as a close observer; in 1882 everything had to be started up, as the camp was new. No houses, roads or trails were built until June, 1881, and every claim had to be first opened and prospected. In 1882 the season was unusually late here, as everywhere else. The late season and the deep snow did not allow the miners to commence work until six or eight weeks later than the year before; then the season has closed early also, although, so far as I can gather data, the camp has produced, for about three and a half months working time, over \$200,000 in dust. This is placer product alone. I have learned that the production of the above amount is distributed among the different claims as follows: The Island claims consisting of Williams & Co., averaged from 80 to 132 ounces per week regularly for twenty-six or twenty-eight weeks. These are the only claims that were able to put in a good season, they being the lowest ones. The Powers claim produced above 25,000; the Harris and Janran about \$12,000 or \$14,000; the Bulger Hill Co., \$15,000 to \$16,000; Grey & Co., \$8,000 to \$9,000; Leary & Co., \$8,000; Franklin claim, \$10,000; Bordrean & Co., \$8,000; Dix & Co., \$10,000; R. Driver, \$5,000; N. Latour, \$4,000; Howe & Co., \$4,000; Hillwell & Co., \$4,000; McGinnis Creek, \$8,000; Lemon Creek, \$6,000, and a large number of small claims that have done equally well. The expense of extracting these amounts has given employment to about two hundred white men at from \$3.50 to \$4 per day, and about four hundred Indians at from \$1.50 to \$2.00 per day.

These amounts of dust were obtained by Ground Sluicing

On top of the quartz ledges, by washing the decomposed quartz through the sluices, and it is no doubt that the percentage of gold saved in this way does not exceed 40 to 50 per cent of the actual value of dirt worked. The gold has to be saved by quicksilver. There are but very few of the claim holders who understand amalgamating. So they most all have but a short string of boxes from 60 to 100 feet long, mostly set at an angle of 6 to 12 degrees, through which is rushed the dirt by turning on every inch of water the boxes will carry, and by rushing boulders through as big as the boxes will carry them. The gold is all small grained, rough (as it comes out of the oxidized quartz), and stands but very slim show to get to the bottom of the boxes, and to come in contact with the quicksilver. Besides, the gold is more or less coated and rusty, our ores being all sulphate ores, and the gold only having been freed through oxidization.

All these placers are

Located on the Hillside

Around the quartz ledges. None are worked in the creek bottoms or gulches, although very good prospects can be gotten in the water-courses, which are only used now as tailing dumps. The quartz mines are still but little explored, and it will take some time and capital judiciously expended to show up the true value of our quartz mines. The best success in quartz has so far been reached through the judicious management of the Alaska Gold Mill and Mining Company by its superintendent, Mr. John Treadwell. This company owns a couple of

Locations on the Douglas Island.

About a half mile across from this burgh, and undoubtedly possess one of the biggest mining properties on this coast. The placer miners, having illegally taken possession of the surface of the company's property, have had for some time several hydraulic giants working on the ledge, wherever the ore is decomposed, in places to a depth of over 10 feet, but they have done good, inasmuch as they have shown up the ledge to its full width, which is over 800 feet at this company's ground, and as wide as 1,300 feet on other points of the ledge. There is a 5-stamp mill on the island. Mr. T. cut into the ledge, which raises from the hanging wall to the foot wall, over 400 feet, and started several tunnels—one at the hanging wall, and several on other parts of the ledge, running south from the foot wall. The ores which were extracted from these tunnels (every particle was

ore) he put through the mill, and it yielded him, in free battery amalgamation, from \$5.50 to \$12 in free gold. The concentrated sulphurets showed a percentage of from three and one-half to eight per cent, assaying from \$85 to \$160 per ton, making an average, so far as worked and tested, of over \$11 per ton. As the tunnel approaches the foot-wall the ore increases in value, as is shown by both milling and placer mining.

It is to be hoped that Congress will before long take final steps to give us some sort of civil government, so as to prove rights and ownership. Undoubtedly with the present prospects the Alaska M. & M. Co. would not hesitate to erect a suitable reduction works, to insure them large dividends, but I suppose they do not choose to start in to much litigation as that might cost more than the mines would justify.

With the mines on the mainland but little has been done, owing to the scarcity of funds. The mill, erected by Webster & Co., was six months in erecting, and, when completed, was so badly managed that nobody wanted to take any ore to the mill to be worked.

There is plenty said and written in this place about mines by persons who never saw a mine in their lives, and who have followed farming, wood-chopping, hay-ranching, etc., until coming here. Yet the public accepts their opinions, and employs them as their agents to show up the merits of this country. Several new districts, and discoveries were made here during the last season; prominent among these are the coal deposits at Murder Cove, at the south point of Admiralty Island. Some very good and large ledges were discovered, located at Montana creek, McGinnis creek and Mount Goat creek, all west of this place on the mainland between here and Lynn canal. Through personal inspection, I found a belt of large and well-defined ledges, carrying high-grade gold ore. The principal one among these is the Telegraph and Alexandre lode, which shows, for a distance of a couple of miles, a strong, well-defined ledge of from 50 to 100 feet in width. Here, also, the placer miners have again followed the quartz prospectors, and, regardless of prior locations, gone to work ground-sluicing off such parts of the ledges as they find to be decomposed. At Cross Sound, near Noonah, is a splendid marble deposit. I visited the place and found a large belt of marble, which carries in its center a stratum about 50 to 100 feet wide, of the purest white fine-grained marble, which will rival any Italian marble.

E. Bean, who spent some months last season between the headwaters of Chilcat and Yukon rivers, brought out some splendid high-grade copper samples, of which he claims he found a large belt of a mile wide and about twenty miles long, claiming it to be about fifteen miles from deep water navigation, covered with heavy timber and near water. The prospecting parties for placers on the Yukon, report satisfactory prospects on the McMillan and White rivers.

Scenery of the Northwestern Archipelago.

The course of the average ocean steamer on the "inland passage" to Alaska, is about as crooked as the most fastidious could wish. For instance, says a *Bulletin* correspondent, we called at Victoria for ship's supplies and for discharge of freight, being detained thus twelve hours. Then we steamed up the gulf of Georgia, directly on our way, for about ninety miles, to Nanaimo, where we coaled under difficulties, from the great Wellington mines. Across the little Departure bay, little more than a pistol shot from the chute of the North Wellington mine, we observed a group of deserted and weather-beaten cabins, on the point of the beautiful little New Castle Island, whence was quarried the fine building stone, for the San Francisco branch mill. Putting off from this same point of land, is the wreck of a pier, reaching back into the bluff and losing itself in the cloud of smoke which day and night lingers in eddies over the same spot. There, we were told, was the famous New Castle coal mine, the oldest of the Pacific collieries, which was abandoned several years ago, because of the unquenchable fire which had been kindled within its walls and filled all its caverns and corridors with death, and thus shutting down one of the finest coal mines on the coast. But I am imitating the digressions of our steamer. From Nanaimo we returned over the same course by which we came from Victoria to Port Townsend. This doubling on our course cost us nearly 200 miles extra travel, and a very annoying delay. Packed with freight, we left Port Townsend at midnight, and in the forenoon of the next day we were off Nanaimo again, on our journey up the coast, and henceforth we had no more delays to speak of, and no particular incident or event worth mentioning.

Grand, but Monotonous Scenery.

For the tourist will see all through this wonderland a thousand things which he can describe neither by mouth, nor pen, nor brush. There is at first a thrill of pleasure, mingled with awe, as one enters this almost limitless sweep of inland, island-studded seas. The charm of the first consciousness that you are being, without a jar or jolt, borne over these narrow seas, almost fathomless in their unbroken depths, winding in and out among tiny islands, covered with forests and veined with various minerals, is well nigh irresistible. The average tourist has no disposition to resist the spell. He surrenders unconditionally. But as

the scene broadens into empires and continents, and sweeps on and on for hundreds of miles in unbroken and unvarying grandeur, the prisoner chafes under the burden of his bondage. There is a surfeit of wonder, the mind reacts, and the traveler would hail with real pleasure the sight of a something common. Indeed, when the morning broke upon us in the little mining village of Harrisburg, there was many an old miner who almost wept as he recognized, in the shadow of mountains of eternal snow, the rude cabin of the gold hunter, and a simultaneous exclamation of pleasant surprise broke forth from our uninitiated passengers.

Harrisburg and its Mines.

At Harrisburg many of our passengers found their destination, at least for the present. Their tents were soon spread upon the rainy beach, and long before night scores of them were off to the gold fields. Strolling, or rather stumbling and climbing through the dripping, mossy, muddy town we found the whole of it mapped off in mining claims, while through the center a sluice was running full of muddy water. Some of the miners gave us good reports from their diggings, but there was what at first seemed to us a puzzling reticence and half-heartedness about even the best reports, by which the hurrying stranger would be easily deceived. But if you could get into the confidence of one of these same men, you would readily have solved the whole puzzle, and you would be prepared better to estimate the miner's confidence in his mines. I found the absence of civil government a serious barrier to all the mining and industrial interests of Alaska. Men, as a rule, are a little afraid to say they have a good mine or a good business of any kind, lest some adventurer in the absence of human law, and regardless of all higher law should dispute their right by superior force, cunning or downright meanness, and thus indirectly rob prospectors of all they have found or can hope to find. I was shown what I am convinced is a valuable quartz mine, one of the largest in the world, I was assured, which would long ago have been fully developed, but for this uncertainty. As it is the proprietors are simply holding it and waiting the dawn of the light of civil government. But in spite of all their rights and their vigilance, large sums have been taken from the "placers" that cover the rock above, while hundreds of thousands of dollars, I was assured by the Superintendent of the mine, have been wasted through careless and slovenly mining by those who have no right to a foot of it. Miners are now scraping up the "tailings" on the beach hundreds of feet below the claim, and washing out in rockers good wages. By the time we were ready to leave Harrisburg at midnight, many of our gold-hunting fellow passengers had "seen the elephant," and armed with tickets for Victoria, Portland or San Francisco, returned by the same steamer that brought them. They were thoroughly disgusted. Others more timid never gave up their staterooms; while others still would gladly have clung to the boat until she had borne them out of the country forever, but, alas, they were "dead broke," and must stay a while longer at all hazards.

Other Mines.

Some of our gold hunters pushed on for the Chilcat country, landing in Pyramid Harbor and packing across the portage to the interior. In about thirty miles they reach the Yukon tributaries. Some good prospects have been found in the interior, I am told, but nothing seems to last. Mines suddenly "pinch out" or wash out. Some good claims which for two years were known to pay \$60 per day to the man, are now entirely abandoned. There are also said to be some good prospects on Admiralty Island, but on the whole I am convinced that the mining outlook in this part of our great northwest Territory is not such as to encourage any great rush. Indeed, I am inclined to utter a kindly word of warning to young men of small means against coming to Alaska for any business just yet. For men of ample means and energy there are no doubt some fortunes up here, but under the most favorable circumstances such fortunes can only be acquired by the hardest industry. However, it must not be supposed that Alaska is poor in resources. Far from it. She is unquestionably rich in fish and furs.

IT WOULD NOT WORK.—The experiments recently made at Tiernan & Co.'s quartz mill demonstrated that the newly-invented Golden Gate sulphuret concentrator will not do the work that was expected of it, and the agent has boxed it up again and bid good-by to the scene of the failure. Tiernan & Co. have ordered two Frue concentrators, which machines have been in operation in all the mills in this district for several years past, and have never yet been found lacking in any respect. They are easy to keep in order, moderate in price, made of durable material, and save a larger percentage of sulphurets than any other ever invented.—*Norfolk Transcript*.

PERSONAL.—Mr. A. T. Dewey, of the firm of Dewey & Co., proprietors of this journal, is residing at Highland Springs, Lake county, with his family. Mr. Dewey is taking a much needed rest from business cares, and his employees trust he will return from his vacation with renewed health and energy.

The Paris municipality has devoted ten thousand francs to defray the expenses of delegates from Paris to the forthcoming Boston exhibition.

Alaska Bears.

The Size, Food and Habits of the Species

(Read before the Academy of Sciences by Ivan Petroff.)

During the past winter, while engaged in compiling maps showing the distribution of fur-bearing animals in Alaska in connection with my report on Alaska, I had occasion to consult authorities on the proper names of the various species of Alaskan bears. With the black bear, *Ursus Americanus*, and the polar bear, *Ursus maritimus*, or *thalassarchus*, there was no difficulty, but it was different with the so-called brown bear of the traders. Dr. Dall, in his list of Alaskan mammals, gives us both the grizzly, *Ursus ferox*, or "brown bear," and the Barren Ground bear, *Ursus Richardsonii*. At this date it is safe to say that *Ursus ferox* does not exist in Alaska, though the so-called brown bear resembles him much in size and disposition. I found him in all parts of Alaska visited by me, with the exception of the Aleutian Islands west of Oonimuk, his range being nearly as wide as that of the fox and mink. Richardson described the Barren Ground bear (subsequently named after him) as of nearly uniform yellowish or brownish color, tips of fur paler on forehead and back; forehead broad, legs long; claws intermediate size, between *Americanus* and *ferox*; dimensions 5 feet 2 inches in length by 2 feet 9 inches in height. This description does by no means fit all the Alaskan brown bears, or even a majority of them, but it comes nearer than any other authentic description at our command, and consequently Mr. F. W. True, of Washington, advised me to adopt for my maps and reports the name of *Richardsonii*, which I agreed to do under protest. With Mr. True I examined over fifty bearskins in possession of the National Museum at Washington, but, strange to say, not one of them was from Alaska, and I was only able to point out those which most resembled the animal I had in my mind. My personal acquaintance with

The Alaskan Brown Bear

Is of long standing. Nearly nineteen years ago, I found myself in a log house on Cook's Inlet, in the month of December, when all bears of regular habits ought to be hibernating and asleep.

One morning, at about ten o'clock, when my lamp was still burning, I heard a rattling at the latch of the hall door. Believing it to be an Indian boy, I opened the door, and saw, instead a bear. Without stopping to ascertain his species, I threw the burning lamp at him, and ran for my rifle, while the astonished animal made for the woods in great bounds. I examined his tracks in the deep snow, and found that I could just fill the impression made by the bear's forefoot with the fingers of both hands widespread, while the hind foot was nearly as long as my arm from the elbow down. My acquaintance with this species was not renewed for some time, but I had frequent opportunities for measuring skins. From fifty measurements I obtained an average length of considerably over six feet, and a distance of three and a half feet between the center of the back and forefoot. In many instances I measured skins of over eight and nearly nine feet in length; one measuring nine feet and nine inches bore evidence of having been stretched. According to my experience, the Alaskan brown bear is fully equal in size to the grizzly, or even the average Polar bear, and certainly much larger than the Barren Ground bear or *Richardsonii*, as described by Richardson himself. The broad forehead distinguishes it from both the white and the black, and the claws are less formidable than those of the grizzly, rarely exceeding three inches in length.

In his habits, which I had many opportunities of observing, the Alaskan brown bear

Differs Much from all Other Species

Thus far described. He does not climb at all; he shuns the timber, except for concealment in the daytime, and exhibits an astonishing predilection for swamp and marsh land, where one would imagine locomotion to be extremely difficult for so ponderous a body. If he hibernates at all, he does so only in the far north. In the continental region south of the Yukon river, the male at least is abroad at all times of the year. He is not opposed to working for his living, and plows up whole hillsides with his claws in search of roots or small rodents. He is also the great road-maker of Alaska. His enormous weight and broad understanding enable him to leave a trail of comfortable width, and, as he is of methodical habits and loves to follow beaten trails, he makes a road easier to follow and travel over than any Indian trail trodden by successive generations. During my earlier wanderings in Alaska, I was often puzzled by finding well-beaten trails along the crest of high, narrow ridges, and in the most inaccessible places, knowing, as I did, that the natives could not be induced to climb even a hill of moderate height. I confess that the road-making is not intentional.

The Alaska Bear as a Fisherman.

As a fisherman, the Alaska brown bear displays skill, ingenuity and prescience. When the salmon begin to ascend the countless streams of Alaska, on their journey of reproduction, the bears repair to the banks and begin operations. Their fishing is done chiefly at night, but in well sheltered spots. I have been able to watch the process in daytime. On the larger rivers, a smooth, sloping bank is select-

ed, upon which the bear stretches himself comfortably and scans the water. If it be clear, the movements of the silvery or brightened fish can be easily followed, but even in muddy streams the bear knows the right time to strike by watching the ripple caused by the salmon's progress. A sudden plunge or sweep with one huge paw and one or more fish are brought out on his extended claws. This is the most common process, but frequently a fallen, half-submerged tree is selected as a point of vantage. In every instance the live fish is carried to some distance from the bank to be eaten and this we must ascribe to reasoning, as later in the sea-

ness of these bears than I am. In disposition the Alaskan brown bear resembles the *ferox* to a certain extent. He will attack man upon the very slightest provocation, and sometimes without any apparent cause. I have seen a bear whom I accidentally wounded at very long range attempt to reach me by crossing a wide river with a six-knot current, to simply avenge himself. The natives in nearly all parts of Alaska consider this bear as exclusively a man's game, while the black bear is much hunted by boys, who shoot arrows into him and kill him gradually, while he endeavors to extract the shafts. On the seacoast both the brown and black bear

saw one skin suspended from the stern of the United States steamer *Thomas Corwin*, which touched the water fully eight and a half feet below the rail. The largest cask at St. Michael's would not hold it for shipment to San Francisco. The shore range of the polar bear in Alaska lies chiefly beyond Bering Strait, but specimens are encountered every year on Norton Sound, and even far down the Yukon delta. Saint Matthew's Island (uninhabited) seems to be a favorite resort of these animals. In this paper I have endeavored to support my belief that the huge, deep-furred, brown-yellow bear of Alaska, with his wide

HERALD ISLAND IN THE ARCTIC OCEAN.

objection to fish, when it is of "high" flavor, than has the Alaska native. One night I watched a huge fellow feeding among the windrows of dead salmon left upon the sand-bars by the receding water of the river. It was quite dark, but the strong phosphorescence of decaying fish made it appear as if the bear was making a meal of fire. In the months of July, August and September berries are plentiful, and the bear begins to vary his diet, subsisting to a great extent upon the most toothsome berries.

In the Coast Regions.

Where the snow does not fall deeply, this food is obtainable nearly all the winter.

Another delicacy much sought after by these bears is the stalk of the wild celery, which

dig clams when the tide is out, and in times of scarcity they do not scorn a meal of seaweed.

The Black Bear of Alaska

Does not range beyond the timber line, and has a strong predilection for mountainous country. During berry season his flesh is quite palatable, though of coarse fibre, but the meat of the brown bear is repulsive to civilized palates at all times of the year. At Prince William's Island, where both the *Americanus* and the *Richardsonii* are found, I have seen skins nearly black, but of coarse texture, of the brown species. In view of the great difference in their habits, I am unwilling to believe in a mixture of the species, and perhaps the change in color can be accounted for in some other way. The natives of that region assured me that the

range of territory, and with habits peculiarly his own, is, perhaps, entitled to the honor of a separate species. Personally I entertain the greatest respect for him, but I have observed him only as an amateur, and must leave it to those who make natural history a profession to fix his exact status, whatever may be his standing among the other *urside* of Alaska.

Arctic Scenery.

In this number of the PRESS is a very interesting account of Arctic currents, referring specially to those on the Alaska and Siberian coast and on Bering Straits. The paper was written by Capt. Hooper, who made the memorable voyage in search of the *Jeanette*. One

THE CORWIN IN A NIP OFF CAPE ROMANZOFF.

son, the dead and half dead fish which cannot get away are consumed on the banks and river bars. Evidently the Alaskan bear has no more grows in bunches on the hillsides, looming up above the luxuriant grass. From the top of a mountain on Kodiak island I watched a family or group of bears, nine in number, feeding on this plant. They proceeded from bunch to bunch, and when I subsequently surveyed the field I found the grass trampled and beaten down around each bunch, but to my astonishment one stalk had been left standing in each instance. The solution of this puzzle I leave to those better acquainted with the true scientific inward-

females of the black bear bring forth their young nearly a month earlier than their off-colored sisters or cousins, which, if true, would indicate a further and corresponding difference, that would effectually prevent an intermixture of the two species.

The Polar Bear

Has been so frequently and so well described that I will merely mention that the *Ursus maritimus* of the Arctic coast of Alaska seem to exceed in average size those described by Richardson, who stated that they do not exceed six feet in length. I

of the accompanying engravings shows the *Corwin* in a "nip," and the other a view of Herald Island. These two engravings are reproduced in the PRESS as matters of interest in connection with Capt. Hooper's paper. They illustrate a character of scenery met with on the coast in winter in the northern latitude.

A cyclone passed over Elberton, Ga., on Sunday evening, killing Bynum Bell (colored), and blowing down sixteen buildings, including three churches.

Alaska.

Something General about the Country—
Geography.

[Read before the Geographical Society of the Pacific by
W. D. PATTERSON, C. E.]

The Territory of Alaska, purchased by the United States Government from the Russian Government for \$7,000,000, the formal transfer of which took place on Oct. 18, 1867, is partly situated between the 130 and 141 meridians west of Greenwich, and the 55th and 60th parallel of north latitude, and partly between the 141 and 165 meridians west of Greenwich, and the 55th, 71° 33' parallels of north latitude. The boundaries may be more particularly described in consonance with the treaty made with the Russian Government in the year 1825, by the British Government. The boundary line by said treaty commences at the head of Portland canal, situated on the 130th meridian of west longitude from Greenwich, and on the 55° 50' parallel of north latitude from the initial point. The boundary line trends along the coast at a distance of thirty miles from the shore line to Mount St. Elias. Thence follows a meridian line from the summit of said mountain to the Arctic ocean. Thence follow the coasts of the Atlantic ocean westward, and the Pacific ocean southeast and eastward to place of commencement. The summit of Mount St. Elias is situated approximately on the 140° 30' meridian of west longitude from Greenwich. The purchase from Russia was regarded at the time as a bad business by the people of the United States. Mock advertisements purporting to come from the Secretary of the State appeared in the daily papers of New York, etc., offering the highest price for waste lands, worn-out colonies and submerged and undiscovered islands, icebergs, polar bears, volcanoes and earthquakes. That Mr. Seward took a correct view of the benefits which would arise from the purchase, has been since amply proved. The area of territory purchased is about 400,000 square miles.

Climate on the Coast.

The existence of a branch of the Japanese warm stream carrying to this coast its waters imposes at the outset the necessity of a high isothermal line along the whole northwest coast of America. The records of the state of the thermometer established the fact. The botany and conchology of the whole region add their certain confirmation. The whole southeast coast of the Alaska peninsula is bathed by these same waters, which retain a high temperature to Kadiak, thence westward this temperature decreases, although the latitude decreases. The report of the botanist exhibits a flora that could not exist in this latitude without an unusually high isothermal condition, accompanied with a great condensation of vapor and precipitation of rain. The influence of the Asiatic current

at the Aleutian Islands is shown by the presence there of two species of *Haliotis*, three species of *Crepidula*, two of *Rissoirella* and other species which are more abundant and range farther north than their allies in the Atlantic. The temperature of the sea water at Sitka in the latter part of July, by observation made there, was at the surface 52° 1', air 54° 9'. At Kadiak Island, the temperature of surface water was 45°; the temperature of air was 48° 9'. Traveling on the same parallel of latitude, the temperature of sea water increases as we journey west.

The mean temperature of the year at Sitka,

renders progress through it very slow and difficult, especially when there is a heavy growth of wood and underbrush. At Fort Simpson, Chilkat, Kadiak, Unalaska and the islands westward this morass exists to the summits, or snow line of the mountains.

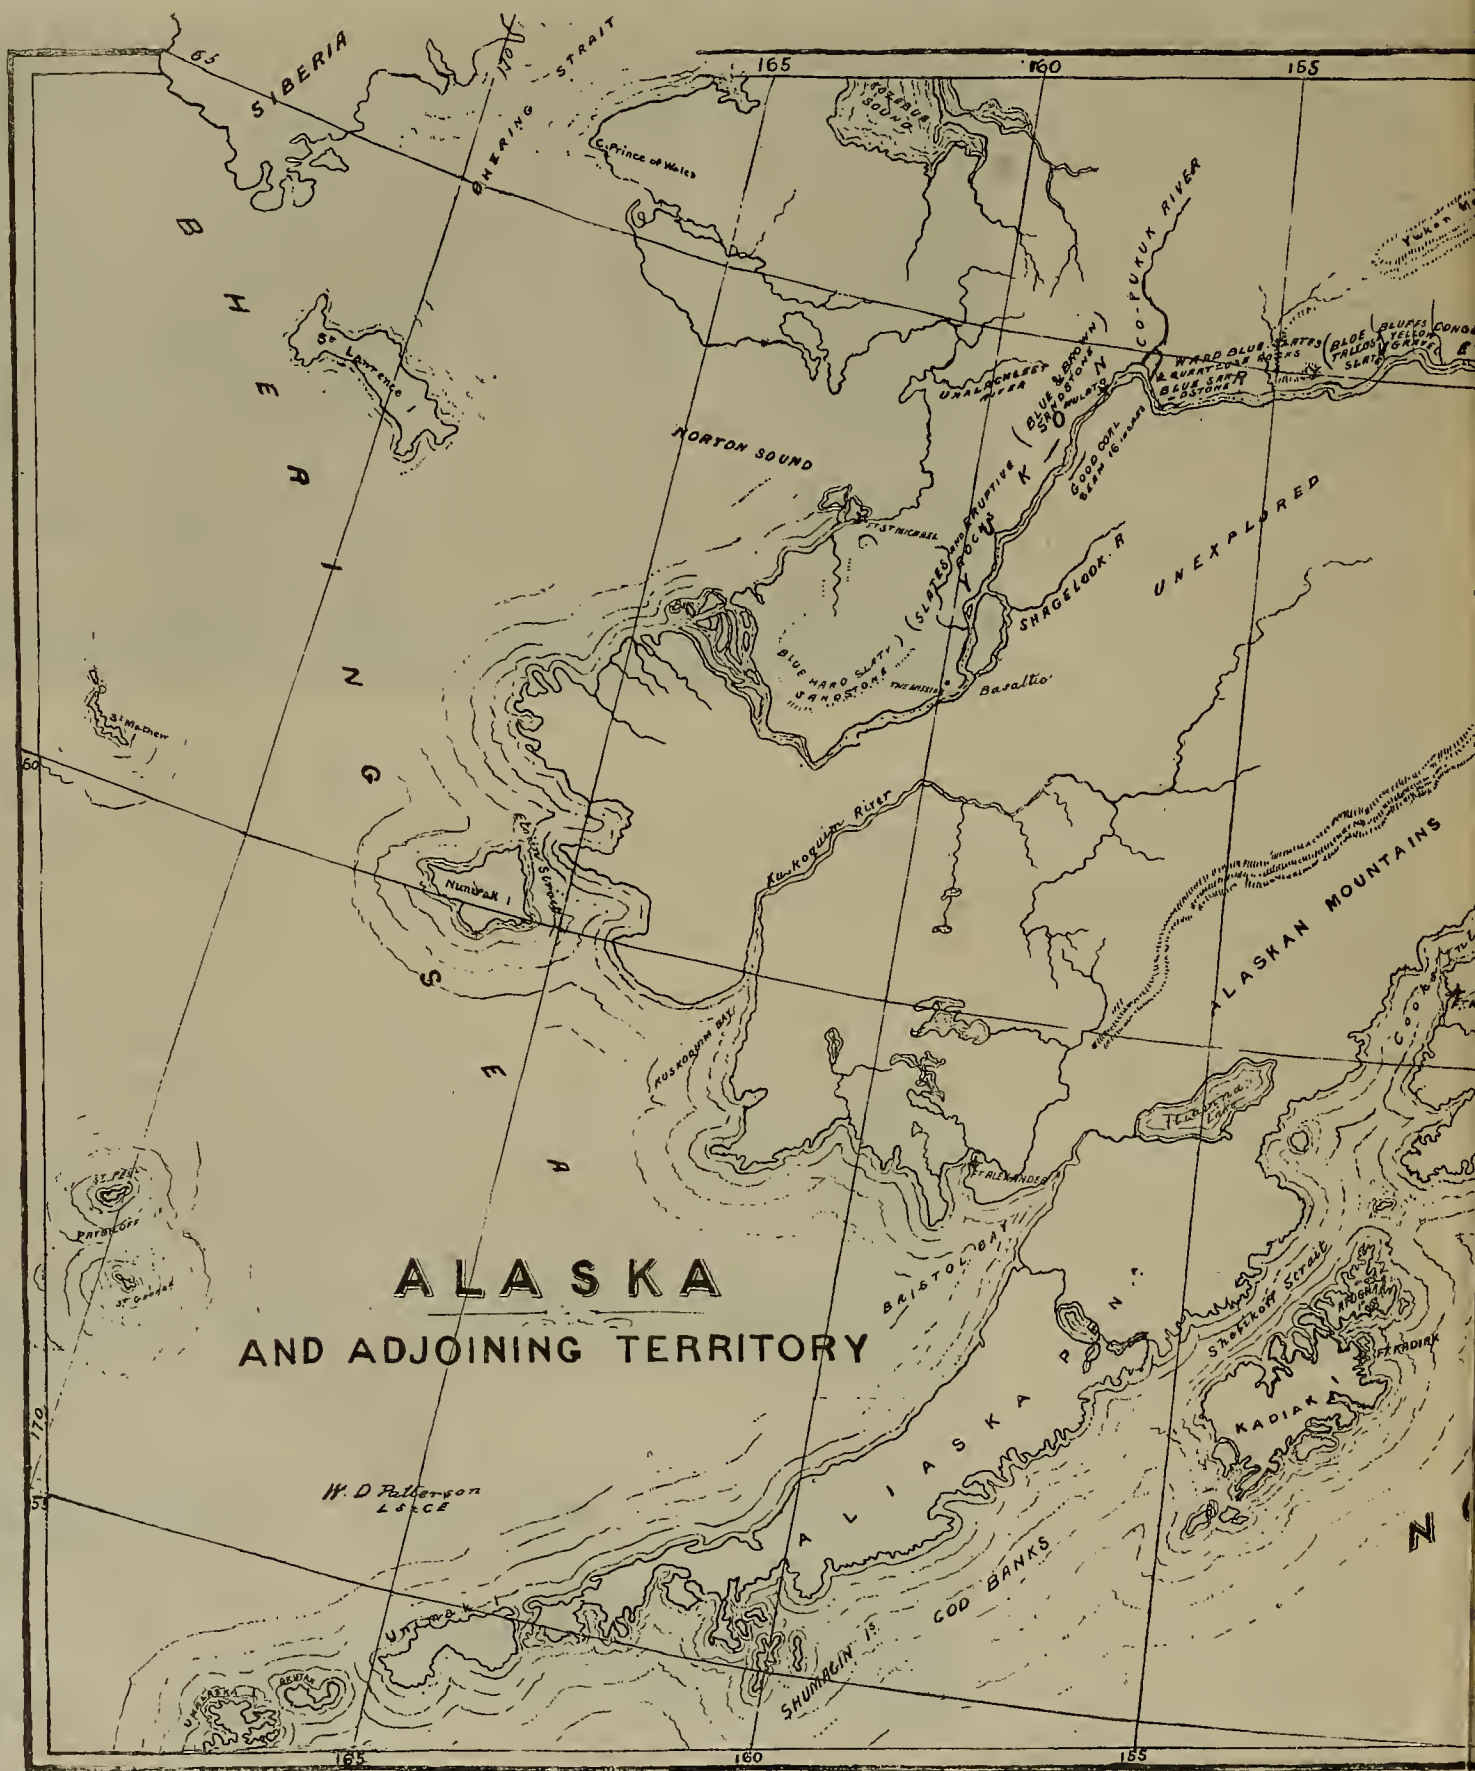

The Prevailing Winds.

In winter are easterly and if from the southward are accompanied with snow and rain; when from the north-east the weather is generally clear and cold. The fogs of New Foundland and Nova Scotia, have an incontestable claim to preeminence from their constant density to

is almost similar in character, being influenced by the Japan current on the north side of the Alaska peninsula, commencing from Bristol Bay and Pribiloff Islands. The Arctic current through Bering strait influences the climate, and the circumboreal fauna common to Greenland, Ochotsk sea and the extreme north of Europe are found.

Early Discoveries

It may here be noted that Norton bay was discovered by Capt. Cook, in the eighteenth century, and was named after Sir. Fletcher Norton, speaker of the British House of Commons.

in latitude 57° 3', derived from twelve years' observations, is 4° 9' Fahrenheit. The mean temperature of the interior of British Columbia, between the parallels of 49° and 54° north latitude is 41° Fahrenheit. The average annual amount of rain melted, snow and hail, that fell from 1847 to 1864 was 82.66 inches. The average rainfall in British Columbia west of the Cascades, in latitude 49° and 50°, is 50 inches. The whole extent of country subject to these rains is covered with *Sphagnum* from one to two feet in depth, even on the steepest hillsides. This carpet is saturated with water, and

those prevailing at Sitka at westward to Kadiak. The stormy weather commences in October and the winter breaks up about the end of March. March, April, May, June and July and sometimes August are good months with an average monthly rainfall not much greater than that on the Atlantic coast. The weather in Cook's Inlet north of 60° of latitude is said to be much better in summer than along the coast generally. The thermometer in summer rises to 95° and in winter falls to 55° below zero. To sum up it may be said that from Sitka westward to the Alaska peninsula the weather

Bristol bay and Cook's inlet were also named and discovered by this navigator.

Vitus Bering, a Dane by nationality, was drawn into the Russian service by the fame of Peter the Great, and his expeditions had been directly organized by that sagacious monarch. Peter did not live to carry them out. Their principal object was to find out whether Asia and America were one, or whether any part of their coasts were contiguous.

The Empress Catharine, as she endeavored in all points to execute most precisely the plans of her deceased husband, began her reign with

an order for the expedition to Kamtschatka. Vitus Bering was appointed commander. On the 4th of April 1728, a small craft was put on the stocks, at the town of Nishui, New Kamtschatka, and on the 10th of July, was launched and named the *Gabriel*. On the 20th he went to sea. Bering followed the east coast of Kamtschatka and Siberia, and discovered the Island of St. Lawrence. He reached as far north as 67° 18', and then found the coast turned to the west, whereon he seems to have come to the conclusion that he had reached the extremity of Asia,

vessels of his fleet got separated by a storm and each had to prosecute the voyage alone. The Aleutian Islands were discovered and other islands near the American coast. Many adventures were had with the natives. Senryv at last made its appearance amongst Bering's crew. They were finally wrecked, on a small island on the Asiatic coast, bearing Russian names were called after Russian navigators and discoverers. Those with English names, namely: Cape Suckling, Admiralty Island, Prince of Wales Island, etc., were named by Vancouver, or Cook of the Royal navy. Cook made a complete survey of

tance from Fort St. Michaels to the Yukon by this route does not exceed 230 miles; by the mouths of the river the distance is approximately 700 miles to the same point. On the morning of the 27th October, 1866 the expedition started from Fort Unalaklik traveling up the river of the same name. On the morning of the 9th instant they sighted the mighty Yukon, and at sundown they broke for the woods and stood on an immense snow-clad field of ice. The mighty Yukon from bank to bank was not less than a mile. This was at the Indian Village Koltag; thence they traveled 33 miles up stream

the building of the fort. Here the Telegraph party wintered. The coldest day for the season occurred on December 5th, when the thermometer fell to minus 58° Fahr., or ninety below freezing, but the weather was lovely and cold was not felt. Their bill of fare for Christmas dinner consisted of Soupe a la Yukon, Arctic grouse roast, Alaska reindeer meat, Nulato cranberry sauce, California preserved peas and tomatoes, dried apple pudding, gingerbread, a la Dali, iced cheese and iced water, winding up with a fair supply of tangleleg, or fire water and pipes. Fine auroral displays were witnessed by them; during the winter one took the form of a graceful, undulating snake of electric light—evanescent colors pale as those of a lunar rainbow ever and again flitting through it, and long streamers and scintillations moving upward to the bright stars which distinctly shown through its hazy, ethereal form. The night was beautifully calm and clear, cold but not intensely, the thermometer at 16° below zero.

The Yukon Tribe of Indians

Is the largest tribe on the Yukon river. They have a wilder and more ferocious cast of countenance than the Nyletes and other tribes. These tribes were much feared by the Russians. Behind the port of Nulato, in a small burial ground, Lieutenant Barnard, of the English, lies. He was landed at St. Michaels Oct. 12th, 1850, and from thence traveled to Nulato. The Indians, after murdering one Russian farther up the river, came down and surrounded the fort at Nulato. They stabbed the Russian commander of the port. The Englishmen fired several shots without effect. A powerful struggle ensued, at last overpowered by numbers they threw him down and stabbed him repeatedly. As they came from his house a Russian shot one Indian from a window, when the rest fled. The reason for the butchery is involved in mystery, but it may be as well to state this case in order that miners ascending the river be put on their guard. I have been obliged to stand guard for some days and nights with others at Penatsind sound, on Vancouver's Island, fearing an attack. The Indians on the coast require firm and kind treatment, and though a shot may never be fired, firearms, always ready for use, exercise a beneficial influence among them. I could, if time permitted, give many instances of Indian attacks and murders on the northern coast to substantiate my statement. The first

and that there was no connection between the continents. In the main point he was right, but he was totally wrong in his conclusion as to the Asiatic coast, commencing its westward course from the point reached by him, he returned to the Kamtschatka river without serious injury to his vessel. The second voyage was undertaken to discover the Pacific shore of America. After much trouble in transporting their goods and building ships, they at last, on the 4th of July, 1741, he went to sea, the port of departure being this time Petropavlovski. On the 20th the

the Alaska Coast as far north as Cape Prince of Wales; and Vancouver afterward sailed over the same ground and differed very little from Cook in observations to fix positions of capes and islands.

Geography and Climate of Interior.

The Ex. Western Union Telegraph Co. expedition up the Yukon started from Fort Unalaklik. By adopting this route they were able to cut off 530 miles. The distance to Nulato by the mouths of the river is 700 miles, but a land route to this place is employed in winter by the Russians traveling from Norton Sound. The dis-

on the ice and snow to Nulato, a Russian trading post.

Nulato is the most inland and also most northern of all the Russian Fur Co. posts. It is on the north bank of the Yukon on a flat stretch of open land bounded on the S. W. by the Nulato river, a tributary of the Yukon. Employees of the Russian Fur Co. were the first explorers of the Yukon Malakoff in 1838, and Derabin the following year reached this portion of the river. In the winter of 1843, Zagoskin of the Russian Imperial Navy arrived, having reached Nulato by the route just described, and he assisted at

Break-Up of the Yukon Ice

Occurred on the 19th of May at Nulato, which is 600 miles from the mouth. It is a mile and a quarter wide in other places. It opens out into lagoons four and five miles wide, studded with islands. It is navigable for 1,800 miles, for large bateaux, or steamers, and skin boats are preferable for voyaging through the ice, as they spring and give, and are not liable to be damaged as a wood canoe.

The Telegraph party made their final start from Nulato, to ascend the river, on the 26th of May. At this time the river was open, float-ice

running in the stream. About a mile above Nulato steep cliffs abut on the west side of the river, showing a blue sandstone formation with shale. Near the Coyukuk river the bluffs terminate on the river in a blue sandstone bluff.

A constant running survey was made by bearings and apparent distances, with many windings. The general direction to Fort Yukon is northeast. The weather was intensely warm, (this was on the second of June), the thermometer standing 72° in the shade. The evening and the early morn are the

Only Times for Traveling

In this country during the brief summer. The heat rises often to 80° in the shade. There is no darkness whatever; a subdued twilight stood in its place, and the sunset glow never left the horizon till it merged in sunrise on the 7th of June. The month of the Tanana river was reached. The country on each side is low and swampy. This was the farthest point reached by Russian traders, and is 240 miles above Nulato. This is a great gathering place for the Indians. In general character, they are good. Immediately above the mouth of the Tanana, the river Yukon narrows. This place has been named by the Hudson Bay Co. the Ramparts, a fortification from the crags and castellated structure, which tower grandly above. A long, low, occasionally submerged island of rocks makes an obstruction in the channel, and the water boils and fumes around them; but there are clear steamboat channels on each side through which the stream runs at the rate of about seven miles per hour. This part of the river abounds with moose deer. They are scarce below this and never found as low down stream as Nulato. They are a staple article of food for the Indians. The meat is excellent; far above deer, or reindeer meat. Moose, properly stewed down is a great luxury. When full grown they average from 700 to 1200 pounds in weight.

After three days' towing the party emerged from the Ramparts. These rapids will be, therefore, about thirty miles in length. The country then opens out low and flat. On the twenty-third of June Fort Yukon was reached. They thus ended their journey of 600 miles from Nulato, occupying 29 days, 26 of which had been engaged in actual travel. Here the sun on the 22d, now the shortest night of the year, set at a few minutes after eleven and rose about quarter past twelve, or the sun was only absent from their gaze 45'. They entered Fort Yukon, giving vent to their feelings in a volley of firearms, which was immediately answered from shore.

This Hudson bay post is now in American territory. The H. B. Co. were always aware that their fort was on Russian soil, but had an arrangement with the Russian Co. about this matter. The goods, confined to trading goods only, were always brought through the whole series of forts from York factory, on Hudson bay, the men of each post contributing something towards their transmission. The employees of Fort Yukon fetch their goods from La Pierre house, a small post at the head of the Porcupine river. This trip occupies them twenty days, camping regularly. A portage of eighty miles has then to be made, over which the goods are

Packed on Men's Shoulders

For the greater part of the distance from Fort McPherson, which is situated thirty miles above the confluence of the Peel river with the Mackenzie. The nearest fort on the Mackenzie is Fort Simpson, distant 1,500 miles from Fort Yukon.

Fort Yukon

Is the most remote of the H. B. Co.'s forts, and is in the high latitude of 67° north latitude approximately. The post was found to be far superior to the Russian post, having newly plastered walls, glazed windows, carpeted floor and open fire-places, and a general appearance of cleanliness. This was the termination of the W. U. Telegraph expedition. Mr. Ketchum and Lafarge, who returned from a trip to Fort Selkirk, when the Telegraph expedition people were at Fort Yukon, reported the river occasionally running through mountain gorges, but navigable for steamboats the whole distance to Fort Selkirk, of 600 miles; supplies of meat and game along the route good, and the Indians everywhere peaceable and desirous of seeing more of the white man. The trip had been made in 29 days, and camping each night ascending, and four days descending the stream without camping.

The General Course of the Stream

Agreed with Arrowsmith's maps. They brought with them from Fort Selkirk two pine cones, determined to be *Pinus contorta*; a variety observed on the River Yukon.

Fort Selkirk has been abandoned by the H. B. Co., on account of the great difficulty of keeping that fort supplied with goods. On the 8th July the telegraph party started down stream for Fort Yukon on their return trip. On the 25d they reached the northern mouth of the Yukon river 65 miles from Fort St. Michaels, and for the first time slept ashore.

General Remarks.

The fisheries of the Yukon are likely yet to be considerably worked. The finest salmon on the coast are found in the river. They are of two kinds, *salmo consuetus* and *salmo dermalinus*. The larger kind sometimes measures five feet in length. This variety is so rich that there is no necessity, when frying it, to put fat in the pan. Other kinds of fish, such as sturgeon, etc., are numerous. The timber on the upper Yukon is mostly birch and maple, interspersed with Arctic spruce, and in last June, 1882, a Mr. Schieff-

lin and his party ascended the Yukon river on a small stern-wheel boat, which they took up with them on a sailing vessel to the mouth of the river. They ascended to the mouth of the Tanana river and established a camp there. Schiefflin then went on a prospecting tour. He made discoveries, and found washings of sufficient importance to justify the detail of a courier to make the long and perilous journey overland to Sitka, in order to convey the news rapidly to his brother in Philadelphia. It is reported that the washings averaged \$1.50 per pan, and that in some instances \$10 per pan was produced. There is a steamer on the river which makes two trips each year. The river is frozen over until about May. For the ordinary prospector with small means, it will be a risky business, and a man must be well fitted out. But I feel confident that paying mines will be found at the head waters of the Yukon and Tanana.

Minerals on the Coast.

At Sitka, fruit trees were introduced in the governor's garden and special attention devoted to their culture, but they have not borne fruit. Berries abound throughout the country in great abundance; potatoes yield well. Turnips, beets, carrots, parsnips and the root crops, with cabbages and the like, are cultivated in a few gardens. Wild peas have also been found growing. Cranberries grow wild and are well flavored.

At Kadiak the weather is somewhat colder than at Sitka. The thermometer has never read below 18° below zero in winter. At St. Paul's vegetation commences in June, and grass springs forward with remarkable rapidity. It is usually out about the 1st of August and cures well and rapidly with a few warm days. The Russian company always kept hundreds of cattle here. Cabbages, carrots, turnips and potatoes are successfully raised. The mean temperature of the air in August is 50°. There are no trees of any size whatever, upon the Aleutian Islands. The timber at Kadiak Island is small, and yet is the source of supply for the Aleutian Islands. At Cooks Inlet the climate is warm. The climate is much milder towards the north than on the Atlantic seaboard on the Eastern shores of America. No forests are found above the month of the river Egg, about the 60° of latitude. On the western they extend as far as latitude 66° 44', or nearly 70° farther towards the pole. The sun being always above the horizon in summer, and the rays falling continually on the surface of the earth prevent the temperature from cooling too much. With the sun thus shining the growth of plants is rapid in the extreme. The snow has hardly disappeared before a mass of herbage has sprung up. The country from Norton Sound to Point Barrow is a vast morland whose level is only interrupted by promontories and isolated mountains. Inland from Norton Sound groves of white spruce are found till in latitude 66° 11' *pinus alba* disappears.

The Minerals on the Coast

On Cooks Inlet there is a vein of coal seven feet in thickness. Coal has also been found at Chatham strait, also at Frederick Sound, vein not very thick.

The most important discovery of coal has been made at St. John's bay, 17 miles north of Sitka, recently. Informants state the coal to be of great thickness and anthracite. It has been burned on a United States steamer, and reported on favorably. Petroleum has been found near Kat-may bay, in latitude 50° 0' 1", longitude 154° 54', abreast of Kadiak island. Three streams meet with in this locality appear covered with petroleum. Specimens of pure copper have been found on the Copper river, about 20 miles above its mouth. Masses of a cubic foot in size have been got here, and the Indians hammer out copper implements from it. Very fine marble has been found close to Sitka. Sulphur is found pure on many of the Aleutian Islands. The Aleutian Islands are all volcanic. A large, rocky island in this chain, known by the Russians as the Pojoslav volcano, rose from the sea in 1796. The spot where the St. Michael fort now stands has been covered by the sea within the memory of Indians. In fact, I have noticed in my travels along the coast, that the whole of the north coast of Cape Flattery, northward, has been suddenly elevated. Hot springs have been found at Sitka. The Indians of the coast are divided into four distinct tribes: the Koloshes, Chilkats, Aleuts and Malmeltes. The extensive sheet of water north of the Aleutian Islands is called Bering's sea, of great evenness of submarine surface at a very small depth. This sea teems with fish. It is marked by several large islands, upon one of which, St. Paul, the fur-seal fisheries are carried on. This Alaska Commercial Co. are allowed to kill 100,000 each year of young males, for which privilege they pay the United States government \$2.50 for each skin. The Shumagin Islands, on the southeast coast of Unalaska peninsula, are famed for the great cod banks in the vicinity. These banks have furnished much of the fish taken to San Francisco. The prevailing forest tree is spruce, growing to the height of 180 feet and four feet thick at the butt. Hemlock, alder and willow are found, but the most valuable wood of the country is the yellow cedar, with a fine even texture, good size and great strength. The terebo will not bore in it and after 21 years' trial at Fort Simpson, the foundation for the fort buildings was found sound, when all other kinds were completely rotten. This timber and the other kinds named cover the coast from Sitka as far north as Lituya Bay.

To Vulture City, Maricopa County, A. T.

[From our Traveling Correspondent.]

Passing from Phoenix, styled by some the "Gem City," and by others the "Garden City" of Arizona, we reluctantly leave the cool streets with the tall cottonwoods on either side, reaching over to touch boughs in the center, and also the cooling streams, trailing a boundary for each sidewalk; the air all fragrant with the scent of many flowers, that so gracefully adorn the front yards of the various dwellings; and as we near the suburbs, the orchard and vineyard, and the blue flowered alfalfa, with the waving wheat and barley fields—all these seem to say with a smile, this is "desert land." A pleasant ride of four miles along the farms brings you to the Grand canal, where you ford on graveled bottom, cooling the horses' limbs and sides. Here the freighters stop in midwater and fill up their barrels, preparatory to making a dry camp that night on the plains. These canals are the arteries of vegetable life on these plains. From this point the roads radiate in different directions across the plains, none of them are favored with a guide board to say "Prescott via Black canyon," Prescott via Wickenburg," "Tempe," Castle Creek, or any of the score of important places to be reached by these roads.

The Traveler

Must get his points and bearings well arranged before he starts, or at this place he will find at least two other roads besides the right road: and should there by chance be campers there, he may find out, that they know less about the roads than he does. But all these guide boards will eventually be erected, when not so much needed. But when on a traveled road across the plains, it is well beaten and not easy to lose that main thoroughfare.

If your animal gets tired you will find places where there is plenty of bunch grass close to the road and can take off saddle and let him eat, and take a lunch yourself. I met some Mormon freighters—they said they would camp at the grand canal that night. Noticing they had no hay, they said they had a hoc with them and would stop on the way and chop some bunch grass—enough to do them with their barley. A pleasant trip of twenty-two miles on this Wickenburg road brings us to Agua Fria or Calderwood's where the water is cold and sweet from a deep well and where they aim to treat the travelers well. Mr. Calderwood has here a stock range, and also has grain and alfalfa lands on Salt river. I met here M. Salsbury, Supt. of the

Benson Smelting Furnace.

And got a few items. The smelter had been running successfully right on as I saw it in March. They lately loaded two freight trains or 30 cars; each with 15,000 lbs. of lead bars carrying large percentage of silver and gold. They now have 10,000 tons ore on dump and 2,000 tons iron ore purchased from the edge of New Mexico. Have all the lime rock needed as flux for 100 years within one mile of the works. The company has ordered another, and larger furnace to be erected immediately which when completed will enable them to smelt 70 to 100 tons per day.

Concentrating Tailings.

He has purchased the Montezuma, a galena mine, near Seymour, from which he has been smelting ores; and also secured by purchase the vast body of Vulture mine tailings at Wickenburg, and has ordered from San Francisco a steam engine and eight large-sized Frue concentrators to reduce the quantity, and concentrate the richest portion, which will be sacked and freighted to Maricopa by teams about 60 miles, and thence by R. R. to Benson to be used as a flux, and also to add much to the value of bullion. This is a large body of tailings and is not a trifling undertaking, but after fully testing, it was considered a feasible, paying proposition, and the parties now in the undertaking mean business.

Mr. Salsbury has made his mark in the State of Nevada and Colorado as a thorough business man, and a success, and all who knew him there, prophesy success for him in all he undertakes here. But Mr. Salsbury's greatest financial success was in the Black Hills mines. His plant at Benson, A. T., gives him the R. R. privileges, being at the junction of the Mexican branch with the S. P. R. R. and well supplied with switches and room to conveniently pile up thousands of tons of ores and fluxing materials. The prospectors can bring their few tons of prospect ore and as soon as sampled and assayed they get their pay for it less \$20 per ton for cost of smelting.

Vulture Mine and City

Is 60 miles from Phoenix, and one of the noted old mines of the territory. To attempt to give any history to do justice to the great energy and perseverance of those who located, or those who followed them in guarding and working this mine would require several long chapters of very thrilling pioneer history.

The Indians were hostile and many, and knew where the few watering places were. The whites had no knowledge of the country except what they learned by very costly experience. Here in the foot hills were some high outcrops of rocks that carried veins of quartz and free gold. But sixteen miles is a long distance to go for water.

About twenty years ago Henry Wickenburg

and Mr. Peoples were prospecting, and accidentally, while seated to rest, Wickenburg discovered the vein of quartz with gold.

The undeveloped, uninhabited country, together with the hostility of the Indians and the great distance from water, made discouragements enough to have caused most persons to forever abandon all idea of working that lead. I am not able to give the names of those who shared in the various stages of the development of this, now great, Vulture mine. As early as 1864-65 they had interested parties with small means, and a road was made through the hills sixteen or eighteen miles to the nearest water privilege and there erected a quartz mill, which made the large pile of tailings lately bought by Mr. Salsbury. But to haul loads of water always back for the use of the mines and the teams, and then to travel with an armed escort of sharpshooters, all helped to increase the expenses of their operations. Mr. Yager, of Yuma was at one time hauling with ten teams, of ten large mules each, from the mine to mill at Wickenburg, to the height of sixteen hands, and of great power at \$10 per ton freight. He had a number of his men killed and lost many animals.

A Mr. Chapman of Los Angeles, was hauling one with eighty mules. He was shot and all the mules were taken. One of his drivers was shot in saddle and falling was crushed by the wagon passing over him. A butcher was shot, and many were the depredations on life and property during several years.

Mr. Hodges, now keeping a boarding-house at Vulture City, was out in this region 22 years ago. He was six years acting as a Government guide, and was at the head of a citizen's organization of rangers.

He says, "I was here with the first miners 21 years ago last June. At that time the Indians were peaceable and friendly. Mr. Peoples and his party came in from California, and discovered rich lead diggings of gold at Antelope. Some of Peoples' party lost a horse by Indians, and they shot two Indians, and then the war began; and the Indians had the best of it, for ten years." Thus many were made to suffer by the brutal rashness of whites, who were too eager to boast of killing an Indian.

There were at one time fifteen arrastras running on the Vulture ore; then a forty-stamp mill. But the very high costs of all necessities, and the losses and depredations, caused a change to be made in location of mill and much loss of time, and expense was the result. A mill was built at Seymore, eleven miles from the mines, thus lessening the distance of hauling the ore and water. This mill also is worn out and torn down years since, and now this property is in the hands of New York capitalists incorporated as the Central Arizona Mining Co. They have erected a grand eighty-stamp mill at the mine, with all the necessary steam power and labor-saving appliances, cars and tracks, self-feeders, etc., so that no hauling is necessary at the mines; an air compressor to supply the mines with good air and furnish the power for the Burleigh drills.

The Water is Pumped

Up from Seymore, or "Pump Station," on an eminence of 300 feet, and flows by gravity from there to the mill in seven-inch iron pipes. To get the supply at Seymore, it is piped in iron five miles to a reservoir, and from this, a large compound Davy engine and pump of fifty-horse power from the Risdon Iron Works, S. F., forces it to the 300 foot elevation. This machinery and the mill has been running two and a half years with excellent satisfaction and without accident.

The immense labor of this pump is shown in the fact that each twenty-four hours the mill and the city requires 250,000 gallons.

The daily consumption of wood at pump and mill is twenty-five cords, worth \$6 per cord at the mill. But next year they expect to burn petroleum instead of wood.

The eighty stamps cease not, day or night for months at a time. The daily capacity of mill is 240 tons. The ore is free milling gold rock of low grade; amalgamate in the battery, and amalgamated plates outside battery. No other devices or concentrators used for saving the gold. The mine is now employing 110 men including those employed in the mill. They now have a foundry to remelt the old castings and make new. McAllister of the Tombstone foundry was just finishing this improvement; 180 tons of old castings were on hand as materials for new castings. This will save a large item of freight expense for dies and shoes. Mr. Hughes, the Superintendent was absent on business, but a prominent person in the town remarked "everything goes on very regular and prosperous since Mr. Hughes has had charge of the works."

Mr. W. H. Davis mining foreman was very courteous in showing me around on the outside works—as was Mr. Barnes the amalgamator in showing me the inside workings.

In the office I found R. P. Todd the financial and legal adviser to be a very pleasant business man, and ready to give information.

As a prudential measure the miners pay regularly each month a small sum to R. D. Johnson, M. D.—who is known as the Co's Doctor. He too I found to be a very agreeable and scholarly young man. The laborers too seemed of the very first class, orderly and sober men. The City of Vulture is a neat little town with a school enrollment of 47 pupils. A neat little society and free reading hall, where the literary society holds weekly meetings for literary and social culture. In these meetings the mill

officials and some of the laborers in mill and mine take active interest.

This mining company can be considered as a rare illustration of how wealth is created and how a large community will really get their support, in a very expensive place, by what can be extracted from a huge outcropping rock of the desert. Good arrangement and good orderly industry accomplishes this, and furnishes even the luxuries of food and clothing to all.

Riotous strikes and interference would here be immediate ruin and desolation.

Some prospecting is still being done in the vicinity and hope of finding rich gold mines, is yet sending out prospectors on every hill and ravine. This Vulture is an immense body of gold quartz, traced and opened for a long distance as a regular vein. This generation will only partially test the resources of this mine.

B. W. CROWELL.

Hunting the Sea Otters.

The sea otters are, according to Scammon in his "Marine Mammals of the Northwest Coast," the most valuable fur-bearing animals inhabiting our ocean. They are caught as far south as 28° north latitude and northward to the Aleutian islands. The full-grown animal may be five ft. in length, including the tail. The head resembles that of a fur seal. The fur is black or dark brown. Otters have been secured along the California coast for many years, but now there are but few secured. Of late they have been shot from the shore by hunters who have wandered up and down in search of them.

The mode of capturing the sea otters between Point Greenville and the Aleutian islands varies with the different native tribes inhabiting that coast. The Aleutians, dressed in their water-proof garments, made from the intestines of the seals, wedge themselves into their *baidarkas* (which are constructed with a light, wooden frame, and covered with walrus or seal skin); and, donning their hunting caps, plunge through the surf that dashes high among the crags, and, with almost instinctive skill, reach the less turbulent groundswell that heaves in every direction. These aquatic men are so closely confined by the narrow build of their boats, and keeping motion with them, too, that their appearance suggests the idea that some undescribed marine monster had just emerged from the depths below. Once clear of the rocks, however, the hunters watch diligently for the otters. The first man that gets near one, darts his spear, then throws up his paddles by way of signal; all the other boats form around him, at some distance. The wounded animal dives

The Signing of the Declaration.

We give on this page a small reproduction of Trumbull's famous painting, "The Signing of the Declaration of Independence." The formal act of separation from the Mother country had been discussed for weeks and finally a declaration was adopted on July 4th, 1776. The final signing of the parchment copy was August 2, 1776.

American tradition has clung to the phrases assigned to the different participants in this scene: John Hancock's commentary on his own bold handwriting, "There, John Bull may read

Change in Railway Trains.

The new time card of the Central Pacific Railroad has been completed, and, unless there should be further changes made by the Union Pacific, the arrival and departure of overland trains will be as follows:

East-bound overland train will leave San Francisco at the same hour as at present. Commencing on the evening of Tuesday, July 3d, the Eastern train will arrive here at 4:25 p. m. instead of 6:55 a. m. as now, and in San Francisco at 8:40 p. m. On the 3d of July there will be two overland trains to arrive, one at

Note for Millmen.

(WRITTEN FOR THE PRESS BY C. H. AARON.)

It frequently happens in mills that bars of bullion are weighed by avoirdupois for want of proper bullion scales and troy weights. The ore assay tables for twenty grammes assays may be conveniently utilized in turning avoirdupois pounds into troy ounces, or in finding the assay value of any number of pounds.

To find the troy ounces corresponding to any number of pounds, consider the pounds as milligrammes got from an assay of twenty grammes of ore, and from the assay table take the ounces per ton which such an assay would give; multiply by ten (move the decimal point), the result is the number of troy ounces which equal the given number of pounds.

To find the value of a bar weighed in pounds, multiply the weight in pounds by the fineness, gold or silver, which gives the number of pounds of either metal in the bar; consider this number as milligrammes of metal from a twenty grammes assay, and from the table find the corresponding value in dollars and cents for the given metal. This value, multiplied by ten, is the value of the bar for that metal.

The fractions of a pound in the bar weight must be written as decimals, a half pound being 0.5, a quarter 0.25.

These methods are easier, quicker and less liable to error than the calculations. They depend upon a coincidence of figures. One milligramme bears the same relation to twenty grammes that one-tenth of a pound does to a ton, namely, 1-20,000; hence the value of a pound of gold or silver is equal to ten times the value, per ton, of ore indicated by one milligramme of either metal, in a twenty grammes assay. The assay tables are to be found in nearly all mills and assay offices, being given away by dealers in assayers' goods.

LOWER CALIFORNIA PLACERS. A dispatch from Guaymas, dated the 26th, says: By the arrival of the schooner *Rambler*, thirty hours from Muleje, the following additional news is brought from the mines direct: Prospecting is being fully pushed and several new and rich placers have been discovered. Quite a party from San Diego have arrived, having landed at the west coast at San Fernando, and thence come to the mines overland. They report good pasturage and water on their route. Small parties are straggling in also from the south end of the peninsula. A company is being formed to bring water to the regions of placers. Luis Garcia and party have struck a rich canyon about six or seven miles from the Mission. Dry washers

THE SIGNING OF THE DECLARATION OF INDEPENDENCE.

my name without spectacles." Franklin's, "We must hang together, or else, most assuredly, we shall all hang separately;" and the heavy Harrison's remark to the slender Elbridge Gerry, that, in that event, Gerry would be kicking in the air long after his own fate would be settled. These things may or may not have been said; but it gives a more human interest to the event, when we know that they were even attributed. What we long to know is, that the great acts of history were done by men

6:55 a. m. and one at 4:25 p. m., having left Omaha twenty-four hours apart.

Coming westward trains will leave Omaha at 12:05 p. m., arriving at Ogden at 7 a. m. of the second day. The Central Pacific train leaves at the latter hour, arriving here at 4:25 p. m. of the second day, arriving in San Francisco at 8:40 p. m. There is here a saving of 14½ hours. Leaving San Francisco at 3:30 p. m. the Eastern train arrives at Ogden at 9:30 a. m., and at Omaha at 7 a. m. of the fourth morning, instead

SEA OTTER HUNTING ON THE PACIFIC—THE ASASKA ISLANDER'S CANOE OR BAIDARKA.

deeply, but soon returns to the surface, near some one of the *baidarkas* forming the circle. Again, the hunter that is near enough hurls his spear and elevates his paddle, and again the ring is formed as before. In this way the chase is continued until the capture is made. As soon as the animal is brought on shore, the two oldest hunters examine it, and the one whose spear is found nearest its head is entitled to the prize.

The number of sea otter skins taken annually is not definitely known, but from the most authentic information we can obtain, the aggregate for the past three years has been 5,000, 1,000 of which came from the Kurile islands; and valuing each skin at \$50, amounts to the sum of \$250,000.

The principal question considered before a Cabinet meeting, one day this week, was relative to the alleged shipment of pauper immigrants to this country, from Ireland, by the British authorities. The result of the deliberation on the subject, is shown in the subsequent action of the Secretary of the Treasury, who telegraphed instructions to the Collector of Customs, at New York, to co-operate with the Commissioners of Immigration, at that port, to prevent all immigrants landing found to be paupers, within the meaning of the law. In the event of such pauper immigrants having already landed, as is reported to be the case with a large number shipped on the steamer *Farnesia*, the Collector is instructed to take all practical measures to have them re-shipped to the port from whence they came.

like ourselves, and not by dignified machines.

Even those who look with the greatest pride and hope upon the present and future of this nation, must admit that the Continental Congress contained in 1776 a remarkably large proportion of able and eminent men. Of the members who took part in that silent drama of 1776, some came to greatness in consequence, becoming presidents, vice-presidents, governors, chief justices, or judges. Others came, in equally direct consequence, to poverty, flight or imprisonment. "Hunted like a fox by the enemy;" "a prisoner 24 hours without food," "not daring to remain two successive nights beneath one shelter"—these are the records we may find in the annals of the Revolution with respect to many a man who stood by John Hancock on that summer day to sign his name. It is a pleasure to think that not one of them ever disgraced, publicly or conspicuously, the name he had written.

INTERESTING EXPERIMENTS.—In experiments made by Professor A. Wagner, with some metals and alloys and water in a certain condition, some curious results were obtained. In water containing saltpetre and air free from carbonic acid, lead and zinc were most violently attacked, tin and Britannia metal only a little, copper, brass and German silver not at all. With air and carbonic acid in the water, zinc and lead were attacked most; copper, German silver and brass were not acted upon by distilled water, while tin and Britannia were affected to some extent. None of the metals showed any signs of dissolution in the absence of carbonic acid.

of at 4 p. m., as at present, making a saving in time of fifteen hours. The Union Pacific has put on a second daily train between Omaha and Ogden, leaving Omaha at 8 p. m., and arriving at Ogden at 6.15 p. m. Returning it leaves Ogden at 9 p. m., and reaches Omaha at 3:20 p. m. The Oregon express will leave at 3 p. m. instead of 2:30 p. m., connecting at Roseville Junction with the west-bound overland, where passengers and mail from the east will be transferred. This will give a much earlier mail to the northern residents.

As to other local trains, what changes there will be has not been definitely settled, but the Colfax train will probably leave at 12:40 p. m. instead of 2:30 p. m., and 3:50 p. m. local to San Francisco will leave an hour earlier.—*Sacramento Record-Union*.

NATURE says there are 12,000 miles of underground telegraph wire in the United Kingdom. The cost of underground wire per mile is four times that of overground, while the capacity of the latter is four times that of the former.

In an interview with an *Enterprise* reporter a few days since, J. C. Flood stated a fact that is not generally known, viz., that for every fifty-five cents of silver mined from the Comstock, there were produced forty-five cents in gold.

It is believed that the Chileans will gradually evacuate the north of Peru under the treaty made with Iglesias, and that he will establish his government, commencing in Trujillo and thence leading towns.

are doing well. By the *Rambler* considerable gold was brought in, but it is almost impossible to find where it is. Three of the passengers who came over have some live pounds, and will return with provisions, etc. Quite an excitement exists here from the news, and confidence in the ultimate richness of the bonanza is freely expressed. The weather is very warm, but nights cool.

RAILROAD MEN IN UNIFORM.—On and after the 1st of July, all conductors, baggage-masters and brakemen on passenger trains in the employ of the Central Pacific Railroad company will be uniformed. The cloth of the uniforms will be navy blue. In summer, employees on the Southern Pacific may substitute blue flannel suits. Caps will be of the same color, railroad style, bell-crowned, flat top, cloth or leather visor, with a small "C. P." hutton at each side. The caps of conductors will have a band an inch and a quarter wide, with gilt braid of suitable width at the top and bottom of the band. Other men will have a gilt braid at the centre of the band. Conductors, baggage-men and passenger train brakemen will wear on the front of the cap metal or gilt-embroidered badges, designating the position of the wearer. Freight train brakemen will not have any uniform.

The last batch of immigrants from the Swinford Union, 100 in number, have gone to Queenstown, for shipment to the United States. It is said the most of them have been in the workhouse.

The Peerless Traction Engine.

We present herewith a cut and description of the lately improved "Peerless" Traction Engine, or road locomotive. The boiler is of the locomotive type, with the steam and water space so arranged that when descending steep grades the water cannot flow to the front end of the boiler, which would expose the top of the firebox, or crown-sheet. The engine is located on one side, near the top of the boiler, with the flywheel and gearing on the opposite side, making it of equal weight, and within easy access of the engineer. A frame formed of wrought iron extends from the front of the firebox to a sufficient distance to the rear of the same, where it supports the platform for the engineer, the water tanks and toolboxes on the top, and coal box under the floor. This frame is carried by heavy steel springs, which rest on stirrups attached to the bearings of the main axle. These bearings are free to slide in a vertical direction, required by the yielding of the springs upon which the entire machine is carried. Said bearings are in every other direction kept in a fixed position by guides formed in the lower end of the side plates (which are the framework supporting the counter shaft and gearing), forming pedestals similar to that of a locomotive. By this arrangement the entire weight of the machine is carried by the springs. The large or master gear wheel, shown in cut, back of the traction wheel, turns on a hollow trunnion, fastened to the side of gear frame. The main or driving axle passes through this trunnion, having sufficient room for the extreme vertical movement of the boiler and all machinery resting upon the springs, avoiding all shocks to the machinery which would be produced by passing over rough and stony roads.

On the driving axle outside of the main or propelling gear is located the compensating gear, which is of a new construction and is made with inter meshing spur pinions, which gear into internal gear-wheels, one of which is formed on the hub of one of the large driving or propelling wheels, which revolves freely on the axle, while the other is an internal gear wheel keyed to the axle which drives the propelling wheel on the opposite side, it being keyed to the axle. The inter-meshing pinions, above referred to, are carried in a wheel between the above named internal gear-wheel. The pinions are in pairs. The pairs gear together one half the width of their face on the wheel which carries them, while the other half gears into internal gear-wheels, accomplishing the same, as does the old bevel wheel compensating gear, and is superior from the fact that there is no side thrust (consuming power) as is the case with bevel gears, thus applying all the power to the gearing in the direction the wheel revolves. This gearing is all enclosed in a dust-proof case. To allow the vertical movement of the boiler and engine being carried upon the springs, and at the same time have a positive connection to the above described compensating gear and traction wheel, there is employed a universal coupling device, very simple and peculiar in construction. It consists of a malleable iron ring which is carried between the main and compensating gears, being connected elastically to the main or driving gear by two links or rods diametrically opposite each other for the forward motion, and two for the backward motion, and then similarly connected from the ring to the compensating gear. These links or rods pass through lugs or projections cast on the compensating gear, having sufficient play in the lugs to allow them to move back and forth when the two wheels change their positions. The rods or links extend far enough through the lugs to hold a series of rubber pads to take up sudden jars and shocks. The links, by being attached at right angles to each other, connecting the ring to the compensating gear, and this to the main or driving gear, permits of vertical movement of the driving gear, no matter how uneven and rough the road may be, and allows of the full power being applied to the traction wheels, without strain, acting similarly to a universal coupling, the ring having somewhat the movement of a gimbal-ring in a surveyor's instrument.

The traction wheels are of large diameter and broad face, the tire being fluted to secure better contact with the earth. The felloes are made of malleable iron, with pockets or recesses in which are inserted the spokes, and are bolted to the tire. The hub is of cast iron, surrounded by an iron ring, with its outer face tapered, and resting on this ring are the spokes, each being provided with a metal plate or heel. The spokes are retained in place by means of a plate bolted to the sides against the hub. Should any of the spokes become loose, they can be simultaneously set out against the felloes by tightening the

bolts in the hub, these drawing up on the tapered ring. By the combination of iron and wood, and the securing of quick adjustment when necessary, it is claimed that this wheel will outwear any other style for the service required.

The motion of the engine is reversed by a new device, using but one eccentric. The advantages claimed over the link motion and all other reversing devices are, that no part of it is in action, except when in the act of reversing, which makes it more durable, giving no trouble to the operator, because requiring no adjusting. It is easy to operate, there being no danger whatever in doing so, even with a full pressure of steam on the valve.

A brake is used by which the engineer can perfectly control the momentum of the engine. A steering attachment is provided, and this, together with the reverse gear, blower, throttle, cylinder cocks, fire door, ash-pan drop, and all parts requiring the attention of the engineer, is within easy reach as he stands on the platform.

This engine is protected by letters patent, granted to Mr. F. F. Landis, and is manufactured by the Geiser Manufacturing company of Waynesboro, Penn.

A Submarine Monitor.

The submarine monitor is the name of an invention by J. H. L. Tuck, an old Californian. It is designed for use in naval warfare and harbor defense. It is a cigar-shaped steel boat, thirty feet long, with six feet breadth of beam and six feet depth of hold, and is propelled by electric motors. The monitor is manned by a

captain and a crew of two men. The captain, equipped in a suit of submarine armor, is stationed on deck. He has the free use of his hands and arms, and although invisible himself, can see distinctly any objects around and above him, and can communicate with his men by telephone. Seated in the stern of the boat is the helmsman, who, by means of a horizontal fish-tailed rudder, controls the course of the monitor, and by observing an indicator, which is in front of him, can tell her exact depth under the water. The third man is stationed at the pumps. He regulates the ballast of the boat and sees that the captain is properly supplied with air. At any time that it is required, he can raise the monitor to within fifteen feet of the surface and take in a stock of fresh air, without making any surface demonstration. It is claimed for the boat that it can thus remain under water for an indefinite time, sail wherever it wills, and rise to the surface or sink to any depth, at the pleasure of its captain. In the event of war, the invisible little monitor would, after sailing about and taking observations, rise under the keel of a vessel, noiselessly attach its explosives, fire them by electricity, and then, guided by the indicator, retire to a safe distance, until the hostile ship was blown out of the water. The plan of the monitor has been highly commended by naval officers and engineers, and it is claimed, that with the services of two of these boats, an attack on our harbor, by any naval fleet in the world, could be successfully resisted.—W. H. Milliken, in the *Engineers' Chronicle*.

MORE ELECTRIC MOTORS.—The cars of the Newark and Bloomfield railroad in New Jersey, two and one-half miles in length, are being fitted with electric motors. One dynamo station, with a 20-horse power engine will be used, and the electric current transmitted along the tracks to the cars. The cars will be run for \$1.25 expense each day of 10 hours.

An Early Celebration.

During the summer of 1848, Company D of Colonel Stevenson's regiment of New York volunteers garrisoned the Mexican town of San Jose, upon the Gulf of California. The writer is under the impression that Lieutenant George A. Pendleton was at that date in command, in consequence of the arrest of Captain Naglee, by order of Colonel R. B. Mason, commanding the department of California, upon charges of shooting, without authority, prisoners of war.

As the Fourth of July approached, the members of the command felt that something must be done to celebrate the anniversary appropriately. The men, the majority of whom were under twenty-one years old, decided upon having a fandango. That was about the only amusement or entertainment possible in that remote place, and was one which they knew would meet the approval of the senoritas, of whom the town could boast a goodly number. The place chosen for the assemblage was about a mile and a half from the Cuartel, and permission was obtained for all hands and the cook (the usual guard excepted) to remain outside the sentry line all night if so inclined. Each participant paid into the general fund "quatro reales," to cover expenses. Three Mexicans were engaged as musicians, the post baker was induced to provide a good supply of cake (a luxury little known to the Mexican population), cordials were provided for the gentler sex, and mescal for the *hombres*.

At that period of the year the days were extremely warm, consequently the "exercises" were delayed until an early hour of the evening. With the setting of the sun, our boys, in small squads, strolled across the Arroyo towards the

The Broken Dam.

The Milton Mining and Water Co. are so well satisfied that the breaking of their large dam was due to human agency that they offer a reward of \$5,000 for the arrest and conviction of the person or persons guilty of the act. It has always been understood that the burning of the brush dam built by the State on the lower Yuba was done by persons inimical to mining, and it is suspected that this dam was also destroyed purposely. At all events, the company is so well convinced of it that they offer a big reward. The dam that was broken last week is situated about twelve miles above Eureka. It lies partly in Nevada and partly in Sierra counties. The dam was built twenty-four years ago, at a cost of \$75,000, and was what is known as a crib dam, being constructed of heavy timbered cribs, filled with earth and rock. Eight years ago it was greatly strengthened at large expense.

It was also raised thus increasing the capacity of the reservoir. This was done by putting a very deep facing of stone on the outside, and also a stone lining on the inside, carrying the comb a considerable height above the top of the old dam. The inside facing of the dam which has an incline of about forty-five degrees, is lined with plank. The sectional width at the base was about 350 feet. The perpendicular height of the top of the dam above the base of the outside escarpment was about 131 feet, but, as the channel, across which it is thrown, has a very rapid descent, the depth from the surface of the water to the toe of the inner face was about 86 feet. The dam itself was about 400 feet long, and the dam it formed back of it was about two and a half miles long, and a half-mile wide. At the point where the dam is located there are three ravines or gulches, which necessitated the embankment of the dam being built in three sections. As the flood swept down the river canyon it carried everything in its path, uprooting giant trees, removing ponderous boulders and playing sad havoc with cabins, bridges and other structures it met with. Back of Graniteville the water is said to have been at least 100 feet high. At Moore's Flat it reached a height of 60 feet. The English dam was owned by the Milton. Their loss will be enormous, as the dam contained a full season's supply of water, without which the company's mines and ditches are useless.

Henry L'choir, acting president of the Milton Company, said speaking of the loss to the company, resulting from the break of the dam, it cannot be computed with anything like accuracy until it is known what property, destroyed by the rush of waters in their course, will have to be paid for. The mere cost of building the dam does not by any means represent the amount of loss. One item alone—the profits the company would have derived from the use of the water that was lost by the breach—is estimated at \$75,000. This figure is set down as the value of the water alone, computed on the basis of the work it would have done. If the company should conclude not to rebuild this year, it loses all of next winter's water supply, thus enforcing idleness on its mines, which are dependent solely upon this source. It is should determine to rebuild this year, in addition to the water lost, valued at \$75,000, the company will have to be at expense of about \$150,000 for construction. The flume which carries the water from this dam to the mine is 75 miles long. With the exception however, of a few boxes near the dam, it is reported unimpaired.

In view of the uncertainty of the outcome of the pending litigation, in which the debris question is involved, the company has not yet determined whether it will be rebuilt immediately, as it does not desire to put \$150,000 in work which they may not be permitted to use after it is completed. The altitude of the reservoir is about 5,000 feet above the sea level, and is located at the source of the Middle Yuba.

The Red Star Line Steamship Company, plying between New York and Antwerp and Philadelphia and Antwerp, is building two new vessels, the *Hesterland* and *Moorland*, each of 5,500 tons register, to accommodate the increasing passenger travel.

GREAT distress is reported among the fishing families along the Labrador coast owing to the detention of spring supplies by a jam of gulf ice along their shores. It is feared that some deaths from starvation have already occurred.

Of forty-two deaths at Damietta (Egypt) Monday, twenty-eight are known to be from cholera. The rest, it is supposed, were from the same malady.

THE PEERLESS TRACTION ENGINE OR ROAD LOCOMOTIVE.

rendezvous, situated about midway between the town and the Gulf. In due time the senoritas also put in their appearance. Many of the male Mexicans hovered around in the gloom, while those more friendly disposed joined in the festivities. The volunteers were indifferent to the feelings of the unfriendly Mexicans, being themselves in sufficient number to repel any assault. They had brought their bayonets with them, suspended to their sides, while some had also pistols. This precaution was a necessity, and no doubt cooled the ardor of the enemy; at least, no occasion arose for their use. The boys enjoyed the evening dance to their full satisfaction, and often afterwards, while they sat at their camp-fires in the gold-diggings, the evening entertainment in the lower country was related.

Over thirty-four years have passed since that frolic, and the majority of those present have long since gone to their last rest. William S. Johnson, James A. Gray, Joseph Sims, Carl Lipp, James Harron; Charles Rosseau, John B. Phillips, Alpheus Young, and George W. Tombs are still residents of this State; while John Wolfe, Alden W. James, George A. Corgan, John A. Chandler, Francis D. Clark, and Jacob W. Norris are residents of the Atlantic States. Of the dead, we recall to memory the genial spirits, Aaron Lyons, Harry Wilson, Hawk Judson, Jack Warrington, John W. Moore, and Charley Ogde. Six nobler comrades it was never the lot of man to associate with; and to this day their memory is ever green to their living comrades of the early Californian days.—July Overland.

LONG RUN.—During the run of the Independence-Navajo mill just closed, at Tuscaraora, commencing on the 20th of July, 1882, and ending on the 10th inst., it has turned out bullion to the amount of \$818,866.42. This, for a mill of but ten stamps, is probably the best record in the State of Nevada.

The Sitka District.

The Southern Division of Alaska.

The people of the United States are taking now very much more interest in Alaska than formerly. Its mines, forests and fisheries are evidently destined to create wealth for the pioneers of the region, though as yet there are comparatively few people in the country. The editor of this journal had an opportunity not long since to talk with Mr. Krause, who spent a winter in the southern division of Alaska, the so-called Sitka district. He had an opportunity of visiting nearly all the principal settlements of the Indians, and the few towns of the white men, in the endeavor to obtain information about the country and its inhabitants.

Mr. Krause says that southern Alaska reminds him in more than one respect of the west coast of Norway. In both countries is met a mountainous coast thickly covered with wood; numerous islands, and between them a complicated system of navigable channels of different sizes; a climate moderated in a high degree by the influence of large oceanic currents; numerous resources and good fishing grounds, and an Arctic scenery of peculiar and beautiful attraction, which is frequented, at least in Norway, every summer season by thousands of travelers. But Mr. Krause agrees with Dr. W. H. Dall, that Alaska is in every respect superior to Norway, and no one who has visited these regions will doubt the wisdom of Seward's policy, although the part of country referred to has not proved, so far, the most valuable one of the whole purchase.

The population of southern Alaska is very small. The number of the Indians will scarcely exceed 10,000, and there are not more than 300 to 500 permanent white settlers. No doubt the country would have a far greater population, but the Pacific coast states and territories being far more attractive, it is not expected that any considerable increase of population will take place, unless newly discovered gold mines prove of high value.

Indian Tribes.

There is also little hope that the Indian tribes will be preserved from the common fate of the red man, notwithstanding the efforts made for their civilizing and christianizing. These Indians belong to the Thlinket people, with the exception of four tribes of Hydas, in the southern part of Prince of Wales Island. It is a remarkable fact that the Thomnets, Hydas and Chymians, although they differ wholly in language and features, have adopted the same customs and the same superstitious beliefs, originated, it seems, by the Hydas.

The most powerful and, unless to a recent date, most warlike of the Thlinket tribes are the Chilcats, at the head of the Lynn channel, geographically divided by a long, narrow peninsula, into the Chilcats proper, settled in two villages at the Chilcat river—one near its mouth and the other some fifteen miles inland—and the Chilcats, at the Chilcat lake. These Indians do not hunt or fish as much as the Thlinket tribes. For many years they have monopolized the trade into the interior, and they are very anxious to keep the white traders and the other Indians from a direct trade with the nomadic Indians at the headwaters of the Yukon river.

Expeditions for trade are organized by Chilcat Indians during the whole year—even in winter. There are two principal routes in the interior, the shortest, but most difficult one is on the eastern side where from the head of a deep channel a branch leads off to the lakes, which empty their waters into the Yukon. They travel no more than three days. From the Chilcat river to another chain of lakes they travel six to seven days. Both routes meet afterwards near the abandoned fort of the Hudson Bay Co. which was once destroyed by a Chilcat expedition. But the Chilcats are not allowed to take the western route.

In winter time they go on

"Snow Shoes"

Manufactured by the Indians in the interior and also by themselves. On both sides they have to cross a glacier. In the interior they do not find so much snow as on the coast. They seldom use sledges and nowhere dogs for sleighing. They carry their provisions and merchandise themselves, or the richer ones by servants, taking as trading goods mostly tobacco leaves and some blankets. In former years the Chilcat Indians went also over the mountains to Yakutat bay where they get sea otter skins but now

the Sitka Indians claim the trail and the Chilcats gave it up.

The Headwaters of the Yukon.

The second river in size in North America, being so near the sea coast, can be reached in three days. This interesting fact will in future time be of economic value. Two years ago, some miners took this route and went down the river nearly as far as Fort Yukon. Others have gone that route since, but it is mountainous and a hard trip.

Local Manufacturing Notes.

MESSRS. SAVAGE & SONS' Iron Foundry is doing a large business at their place on Fremont St., S. F., employing the best class and skillful workmen.

The Tonite Powder Co., 218 California St., S. F., report a good trade with increasing orders. They make a high grade powder, quite popular among consumers, and enjoy a good trade accordingly.

ONE of the best known manufacturers in the line of oak tanned leather belting is L. P. Dege, whose factory at 128 and 130 First street, S. F., is prepared to furnish, at short notice, the best rawhide lining, cut strings and sides. Liberal discounts are given on large orders. The products from these works enjoy good repute.

THE Mechanics' Foundry, located at Nos. 213 to 219 First street, S. F., are running full with orders and are doing first class work. They manufacture to order quartz mills and all kinds of machinery castings, stove plate, light, fine and smooth castings, car wheels, gas and water pipe, etc. The officers are John C. Quinn, President, and G. W. Kelley, Business Manager.

The Columbian Foundry at 133 and 135 Beale St., are quite busy in the manufacture of house fronts and machinery castings of all kinds. Mr. Reese Llewellyn the proprietor of these works is also patentee of the Llewellyn's Heater Filterer and Condenser for steam boilers, a mechanical contrivance simple and useful. It is claimed for the Patent Filterer, Heater and Condenser that it saves fuel, water, labor, wear and tear of tubes and plates, repairs and also risk of explosion. The saving in water alone is said to be 33%. Among the many testimonials already given to the inventor, who strongly recommends its efficacy are the C. P. & S. P. R. R. Co's, Union Pacific R. R., Mare Island Navy Yard, the N. O. Mint and many others.

MR. L. MILLER, JR., of 335 Bush street, S. F., has made quite a reputation lately, having secured the contract and been awarded first prize for the manufacture of the elegant and rich trophy, made of solid gold and silver only, to be contested for in a competitive drill of the Knights Templar, during the coming Conclave this summer. It is a veritable work of art and can be seen at his studio, 335 Bush street, where he is also engaged in manufacturing jewelry and diamond setting, working in quartz, moss-agate, mineral and cabinet jewelry. Quartz specimens bought and sold.

Banking.

The Bank of California still maintains its position in the front rank of banking, with a capital of \$3,000,000. This bank is one of the best advertised concerns in its line throughout the United States. A large foreign business is transacted, and they have a branch at Virginia City, with correspondents in all prominent mining centers, which is a feature of this institution. The officers are: Wm. Alvord, President; Thos. Brown, Cashier; B. Murray, Jr., Assistant Cashier.

A conservative firm of good repute are Messrs. Sather & Co., bankers, located on Montgomery street, corner Commercial, San Francisco. Mr. J. S. Hutchinson is cashier of this bank. They make a specialty of bills of exchange and telegraphic transfers on Drexel & Co., of New York and Philadelphia, and make collections in all parts of the United States, issue letters of credit, and draw bills of exchange on London, Paris, Hamburg, Cologne, Berlin, Bremen, and chief cities of Europe.

Among the leading banking institutions in San Francisco is the First National Gold Bank. The institution has a paid-up capital of \$1,500,000, with a surplus fund and undivided profits of over \$300,000. A general banking and exchange business is transacted, and drafts and commercial credits are sold on principal cities of the United States and chief cities throughout the world. The officers are: D. Callaghan, President; G. A. Low, Vice-President; E. D. Morgan Cashier—the directors being composed of prominent and substantial citizens.

SULPHURIC ACID FUMES IN CONSUMPTION.—It having been observed that, in connection with a manufacturing process, involving the production of slight fumes of sulphuric acid, and which has been carried on for 44 years in the vicinity of London, not a single instance of consumption had occurred among the great number of workmen employed, the natural inference was that the immunity was due to the acid fumes. The director of the manufactory—a pupil of Liebig—has hence suggested that a new method of treatment for consumption should be adopted, by bringing the patients into contact with an atmosphere moderately charged with sulphuric acid.

Make yourself healthy and strong. Make life happy by using Brown's Iron Bitters.

About Obtaining Patents.

Patents are Virtually Contracts

between inventors and the public. The consideration flowing from being parties to the contract is expressly made by statute. The government requires the following consideration in every case: First, that an applicant for a patent shall disclose a new and useful improvement, of which he is the first and original inventor. Second, that the invention has not been patented, or published in any printed publication prior to the date of his invention. Third, that the invention has not been in public use, or on sale, more than two years prior to his application for a patent. Fourth, that the invention shall be properly described and claimed in the specification forming a part of the patent. Provided an inventor complies strictly with these conditions, the Government guarantees that the inventor shall have the exclusive right to make, use and sell the thing invented for the term of 15 years.

The Patent Law provides that in case a patent, which is the evidence of the contract, is not executed in compliance with the requirements of the law, it may be annulled and rendered void. Hence, it is of the greatest importance to every inventor that his patent or contract be skillfully and accurately drafted, that it may afford him complete protection for his invention during the life of his patent.

Secure a Good Patent.

An inventor should first ascertain whether or not his improvement has been patented to another. This requires an exhaustive search among all the patents in the class to which his invention relates. This question can often be answered gratuitously by an inventor, or by a respectable firm of attorneys of the invention, by reason of our long and extensive practice as patent solicitors and editors and publishers of first-class, scientific and industrial journals, during the past 20 years, we have been in the habit of priority of invention is not so readily to be determined as it is generally thought to be. It is termed a "preliminary examination," by searching through the patent office reports among the patents in the class to which the invention relates, and referring to our extensive patent library, containing copies of all the special classes of American and foreign inventions, mechanical dictionaries, scientific encyclopedias, files of scientific and mechanical newspapers, and an immense number of patent applications by inventors of the Pacific coast, carefully filed by this office since 1829.

If, by this "preliminary examination," the improvement is found to have been previously invented, our client will receive, for the small sum of \$5 for the examination, a verbal or written report, advising definitely whether his invention has been anticipated, thereby saving him further expense and perhaps much time, useless delay, anxiety, etc.

To avoid all unnecessary delay, however, in securing patents at the earliest moment practicable, inventors will do well to send us an application for a patent well prepared, containing a full and comprehensive description of their invention, and distinctly what the particular points of improvement are, with \$15 as a first installment of fees. If the improvement appears to us to be novel and patentable, the necessary papers for an application for a patent will be prepared immediately, and forwarded to the inventor for his signature. When the inventor receives the application and finds it duly prepared, he will carefully sign and return the same promptly addressed to us, with postal money order or express receipt for our own fee. The case will then be promptly filed by us in the Patent Office, and vigorously prosecuted to secure the best patent possible. (This course is the most expeditious and satisfactory, as no time is lost in transcribing copies of the drawings for the Patent Office, and the steps to be taken.) When the patent is allowed the inventor will be duly notified, and on sending the final Government fee of \$20 to us, we will order the issue of the patent, and forward the same as soon as it is secured from the Patent Office.

The payments are thus divided and made easy. We make no pretense of doing cheap work, in order to entice custom, nor do we afterward make additional charges to bring the bill up to a fair compensation. We do our work honestly and thoroughly for our own fee. The case will then be a chance to obtain a patent. The Agency charge is from \$25 to \$30, or sometimes more, if the invention is intricate or complicated, or requires much labor. Drawings cost from \$5 upward, according to their number and the complexity of the invention. A model is sent, the express charges upon this and the papers must be added. The total cost, in addition to Government fees, rarely exceeds \$40, and for this we do all we can without appealing the case.

When a model is required, a full article of manufacture, or a new composition, samples of the separate ingredients sufficient to make the experiment and also of the manufactured article itself, must be furnished.

Models and Drawings.

Models are now seldom required by the Commissioner of Patents, and generally only in intricate cases. Perfect drawings of practical working machines are considered more satisfactory than the old and cumbersome system of storing up an immense bulk of all sorts of miscellaneous models.

Drawings or sketches sufficient to illustrate clearly the invention, with a sufficient description to enable us to make a full set of perfect drawings for the Patent Office is all that we require. A model will answer our purpose as well, however, in cases where the inventor can more easily furnish it for our use.

The value given for the validity of a patent often depends on the character, clearness and sufficiency of its drawings. There are thousands of existing patents in which the improvements are but partially or very poorly illustrated in the drawings. When an attempt is made to dispose of such patents, the deficiencies and weaknesses of the drawings often prejudice capitalists and manufacturers against the invention, while in reality it may be of great value, and would meet with ready sale had the invention been fully portrayed by artistic and skillfully executed drawings. Again, when patents are brought into court, the uncertainty and ambiguity of the drawings enable the opposing experts to mystify the judges as to the construction or combination of parts intended to be covered by the patentee. In all cases, therefore, the inventor should make use of our personal supervision by skilled draftsmen in our constant employ, and every precaution is taken that the invention is fully and clearly shown by different views, so that the improvement will be readily understood by the examiners in the Patent Office and comprehended by the public when the patent is granted.

In the Patent Office

The application is assigned to the Examiner having charge of the class to which the invention relates. The case must then take its turn with others in the order of filing, and in due time is carefully examined to test the novelty of the invention. If the examiner fails to find anything that anticipates the invention, a patent is immediately issued, provided the specification and claims are drafted in proper form. Should the Examiner find a prior patent which, in his opinion, anticipates one or more of the claims in the application, a letter of rejection is sent to the attorney in charge of the case, and if the attorney coincides with the views of the Examiner, the claims rejected are erased. In preparing applications for patents, an attorney should be careful to familiarize himself with the class of inventions to which the application pertains, so that the specification and claims may be drafted as nearly perfect in the first instance as is possible. This course saves much time in prosecuting the application to a patent.

When claims are improperly rejected on patents which do not anticipate, a patent is immediately issued, and our steps are immediately taken to convince the Examiner of his error. This is done, in most part, by personal arguments, as the differences in construction, operation, function and results are more readily discovered and appreciated by an oral presentation of the facts than can possibly be done by relying solely on written arguments. In order that the Patent Office record of the patents shall be complete, an oral argument is generally supplemented by a manuscript brief, that contains a summary of the points of novelty, and may clearly comprehend the position taken by the Examiner and attorney in prosecuting the case to a patent.

In addition to our own personal attention to the interests of our clients, we have, since 1829, maintained our own law office in association with us in Washington, one of the foremost legal counselors and ablest of practitioners in patent business in this country, who carefully attends in person to our business at the Patent Office, and has attained success in a most remarkable degree.

Perfect Claims

The value and force of a patent are dependent on its claims. A patent is of no value to the public in the most important and valuable invention, and yet the claim be of such meager scope that the patent is actually worthless. When the claims of a patent are so loosely drafted that infringers can defeat the market with their improvements, deriving from the improvement disclosed by the patent only in slight changes in construction and arrangements of parts, such a patent is valueless to the owner, as it fails to afford him that exclusive and complete protection guaranteed by the

Patent Law. Hence it is that the greatest care, skill and perseverance are required, first, in properly drafting the claims in the first instance, and second, in prosecuting the application before the Patent Office, and maintaining the rights of the inventor to claims as broad and sweeping as the invention will warrant. This latter is no easy task. The Examiners of the Patent Office serve in the capacity of attorneys guarding the interests of the public. It is their duty to exercise the greatest care and watchfulness, that patentees do not secure claims of greater scope than they are justly entitled to. It is but natural that Examiners are sometimes in error as to just what scope should be accorded an invention. Although the Examiners act under a sworn duty to not secure claims of greater scope than the inventor is justly and fairly entitled to the claims of his invention, if he is convinced that they are just and proper. To succeed in this requires the display of tact, firmness and ability; and when the Examiner is made to see that the inventor is honestly and fairly entitled to the claims which have been rejected, he will almost invariably recede from his former action, and allow the case.

Advantages to Inventors on the Pacific Coast.

The firm of DEWEY & CO. (continuously editors and publishers of the MINING AND SCIENTIFIC PRESS) have commenced in 1850 their comparative far better facilities to the local inventors of the Pacific States and Territories than are possessed by any other agents in America. Members of the firm have been in the habit of the applications entrusted to their care. They have been longer in practice in patent soliciting than most agents who are still personally engaged in the business. They have secured U. S. and foreign patents in the past 20 years (with very few exceptions) than any other firm still existing. Their practice has been so successful and long continued, that the great majority of inventions on this side of the American continent have been patented through their agency, thus affording them great and valuable experience, by thorough information of the true principles and points of novelty in the inventions, whether general in character or peculiarly local to this coast.

Their extensive business combination and experience of this nature, is undoubtedly one of the most fortunate in existence for affording inventors prompt and reliable advice, and the best possible facilities for securing their full patent rights with safety and dispatch at uniformly reasonable rates.

Every patentee of a worthy invention is guaranteed the gratuitous publication of a clearly-stated and correct description of his invention, in one or more of our influential and reliable newspapers, affording just the circulation that is best calculated to widely inform the class of readers most specially interested in the subject of his invention.

Saving of Time Etc.

Inventors on this coast will find that owing to our familiarity with inventions and local affairs of the coast, we can more readily and fully comprehend their wants, and thus save much of the time ordinarily consumed in preliminary writing back and forth when distant agencies are employed.

Caveats.

A caveat is a confidential communication made to the Patent Office, and is therefore filed within its secret archives. The privilege secured under a caveat is that it entitles the inventor to receive notice, for a period of one year, of any patent subsequently issued, and which is adjudged to be novel, and is likely to interfere with the invention described in the caveat, and the inventor is then required to complete his application for a patent within three months from the date of said notice. Caveat papers should be very carefully prepared. Our fee for the service varies from \$10 to \$20. The Government fee is \$10 additional.

To enable us to prepare caveat papers, we only require a sketch and description of the invention.

Rejected Applications.

Inventors who have rejected cases (prepared either by themselves, or for them by other agents), who desire to ascertain their prospects of success by further efforts, are invited to avail themselves of our unrivaled facilities for securing favorable results. We have been successful in securing Letters Patent in many previously abandoned cases. Our terms are always reasonable.

Inventors who do business with us will be notified of the state of their application in the Patent Office, when it is possible for us to do so.

DEWEY & CO.

Patent Solicitors, Office of MINING AND SCIENTIFIC PRESS, 252 Market St. Elevator entrance, No. 12 Front St., S. F. GEO. H. STROMG. W. B. EWRE. A. T. DEWEY.

Our Agents.

OUR AGENTS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. McGREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JACK C. HOAG—California.
B. W. CHURCHILL—Arizona Territory.
M. H. JEWELL—Barre, Vt.
I. M. LEWIS—Los Angeles, San Bernardino and San Diego counties.
A. C. KNOX—Oregon and Washington Terr.
J. J. BARTELL—Yolo county.

Successful Patent Solicitors

As Dewey & Co. have been in the patent soliciting business on this coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That this is understood and appreciated is evidenced by the number of patents issued through their SCIENTIFIC PRESS Patent Agency (S. F.) from week to week and year to year.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$4 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times,) by turning a leaf.

OUR PATENTIZER.—The rotary oil pulverizer, advertised in another column as for sale by Mr. Heald, has been used by very slightly, and is a bargain to any one in want of a new machine. It is only sold because the company which ordered it is dissolved, and there is no possible use for it. All the necessary gearing, frame, etc., go with the pulverizer, which can be set running in half an hour after it is received. Parties needing something which will grind ore in time, will do well to communicate with Mr. Heald concerning his machine.

IMPORTANT additions are being continually made in Woodward's Gardens. The grove walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

Metallurgy and Ores.

Nevada Metallurgical Works,

No. 23 STEVENSON STREET.
Near First and Market Streets, S. F.
ESTABLISHED, 1869. C. A. LUCKHARDT, Manager.

Ores Worked by any Process.
Ores Sampled.
Assaying in all its Branches.
Analyses of Ores, Minerals, Waters, Etc.
Working Tests (Practical) Made.
Plans and Specifications furnished for the most suitable process for working Ores.
Special attention paid to Examinations of Mines, plans and reports furnished.

C. A. LUCKHARDT & CO.
(Formerly Huhn & Luckhardt.)
Mining Engineers and Metallurgists

JOHN TAYLOR & CO.,

IMPORTERS OF AND DEALERS IN

Assayers' Materials, MINE and MILL SUPPLIES,

CHEMICAL APPARATUS AND CHEMICALS, DRUG
GISTS' GLASSWARE AND SUNDRIES, Etc.

118 and 120 Market Street, and 15 and 17
California St., San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoria, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods both as to quality and price. Our New Illustrated Catalogue, with prices, will be sent on application.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application. Agents for the Patent Plumbago Crucible Co., London, England.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First St., a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. Reference as to above can be had upon applying to this office.

INGERSOLL ROCK DRILLS

AND

AIR COMPRESSORS

Mining Machinery.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x30. This latter size furnished J. P. Haggin for Olant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars. McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

CONTINENTAL WORKS, BROOKLYN, N. Y.

Duc's Mechanical Atomizer or Pulverizer.

For reducing to an impalpable powder all kinds of hard and brittle substances, such as QUARTZ, EMERY, CORUNDUM, GOLD AND SILVER ORES, BARYTES, COAL, OCHRE, MANGANESE, IRON ORES,

PHOSPHATE ROCK, ETC.

It is simple and not liable to get out of order. Revolving Shell being constructed of Siemens-Martin steel, and all parts mechanical in design and of first-class construction. Weight 5,500 lbs.; heaviest piece, 1,500 lbs. It will pulverize 7 to 10 Tons in 10 Hours with 30 H. P. For circulars and full particulars apply to or address,

PATENTS AND INVENTIONS

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR WEEK ENDING JUNE 19, 1883.

279,694.—TRANSMITTING POWER FROM A CENTRAL STATION.—John L. Boone, S. F.
279,640.—DRY ORE SEPARATOR.—M. B. Dodge, S. F.
279,641.—SEPARATOR FOR WET ORES.—M. B. Dodge, S. F.
279,643.—MINING KNIFE.—Catharina Gilberts, S. F.
279,745.—TAP AND FAUCET.—Gregg and Briody, Santa Cruz.
279,750.—RASP.—S. T. Harrison, S. F.
279,758.—ADJUSTABLE HORSESHOE.—Peter Hicks, Napa, Cal.
279,769.—SAW-SWAGE.—Simon Kinney, Port Townsend, W. T.
279,770.—ADJUSTABLE GRATE.—Frank Knox, Woodland, Cal.
279,878.—PHOTOGRAPHING MOVING OBJECTS.—E. J. Maybridge, S. F.
279,603.—FAN WHEEL.—W. Schmolz, S. F.
279,831.—LINK PROTECTOR.—A. V. Smith, S. F.
279,834.—DRILLING MACHINE.—Jas. C. Smith, The Dalles, Or.
279,613.—WHEEL HARROW.—Thos. A. Sweet, Cambria, Cal.
279,675.—CAR COUPLING.—S. G. A. Urquhart, S. F.
279,719.—FRUIT DRIER.—A. Crawford, Sebastopol, Cal.
13,992.—DESIGN BADGE, OR EMBLEM.—Philip H. Kinn, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through DEWEY & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

AUTOMATIC ADJUSTABLE GRATE.—Frank A. Kuore, Woodland, Yolo Co., Cal. No. 279,770. Dated June 19, 1883. This invention relates to a new and useful adjustable grate, the operation of which is automatic, and it consists in the details of construction of a grate supported by the free ends of levers pivoted at opposite ends in the fire-box, and in a means of operating a weight upon the outside of the box for raising the free ends of the supporting levers and elevating the grate as the coal is consumed. The object of this invention is to keep the fire near the top of the fire-box, no matter what the state of the coal may be. Adjustable grates depending upon the direct operation of some person, and which, when adjusted and set, remain so until again altered are common, but the object of the inventor is to furnish a grate which shall adjust itself by rising as the coal is consumed, so as to keep the fire near the top.

TAP AND FAUCET.—Isaac N. Gregg and Edward Briody, Santa Cruz, Cal. No. 278,745. Dated June 18th, 1883. This tap and faucet consists in a pipe or tap screwed permanently into the vessel, and provided with vents or ports at its rear end. Within this end is screwed a solid plug, the threads of which, when under the ports, close them, but when moved, lock open them, so that the fluid may find an escape by the smooth portion of the plug, which is of sufficiently smaller diameter to form such a passage. This plug is operated by a faucet, the end of which is provided with a mortise; the faucet screws into the tap and engages with a tenon upon the end of a plug, said tenon only reaching into the mortise far enough to leave a passage through the latter into the faucet. The object is to furnish an effective tap and faucet, and one in which the parts are not liable to bind or otherwise get out of order.

ADJUSTABLE HORSESHOE.—Peter Hicks, Napa, No. 278,758. Dated June 18, 1883. This invention relates to certain improvements in horseshoes, by which the inventor is enabled to so adjust them to the hoof as to allow the latter perfect freedom to expand both at the front and rear. It consists of two curved bars fitting the sides of the hoof and meeting at the front. These bars are made straight or flat across the front edge, and may have a dovetailed groove or projection across their front edges to receive a transverse bar, which is correspondingly tongued or slotted to fit the front of the side plates as one, while it allows them so separate sidewise to accommodate the expansion of the foot.

CAR COUPLINGS.—Samuel G. A. Urquhart, S. F. No. 279,675. Dated June 19th, 1883. This invention relates to certain improvements in car couplings; and it consists of a novel construction of a bumper loosely supported from its rear end, of a spring-actuated coupling-pin, of peculiar form, and lever connections by which the pin link may be raised for the admission of an approaching link, so as to couple therewith; and of certain details of construction. By this

coupling there is no necessity for going between the cars, as the link can be raised either from the top or side of the car.

LINK PROTECTOR.—Andrew V. Smith, S. F., Cal. No. 279,831. Dated June 19th, 1883. This invention relates to a new and useful means for protecting links from wear by friction, whether the said links are used in a chain or singly. It consists in a peculiar independent, removable bearing, adapted to fit and to be wedged or keyed into the end of the link. The object of the invention is to prevent wear of the link.

FRUIT DRIER.—Adam Crawford, Sebastopol, Cal. No. 279,719. Dated June 19, 1883. This fruit drier consists in an iron frame or building constructed in a peculiar manner. The object of the invention is to provide a strong and durable apparatus adapted to withstand the heat, being fire-proof, and especially adapted for the circulation of the heat.

DESIGN FOR A BADGE.—Philip H. Rinn. Dated January 19, 1883. This invention relates to a novel design for pin, badges or emblems which are made in the form of a maltese cross; and it consists of a mosaic or inlaid work of squares upon the arms of the cross so as to imitate a tessellated pavement in perspective.

Enlarged Issues of the Mining and Scientific Press.

It is the intention of the publishers of this journal to spare no enterprise in advancing the future interests of its readers by all reasonable and practicable methods. Among other advances, we contemplate issuing soon several extra sized sheets, especially devoted to different important localities. The next will be on

Utah Territory, July 2nd.

We shall issue a special double edition about Utah has won for herself a bright name from her many dividend paying properties, and each year her mineral resources are being more and more developed. The mines are scattered over a wide region and are in great number. The record of bullion shipments is highly encouraging in the interests of legitimate mining. A general description of the mining regions with such maps as will aid in illustrating the location of the districts, will be given in this edition.

Other double editions will follow shortly after, which will be devoted to the special interests of other mining localities.

All these regions possess more or less interest for California and San Francisco. We ship goods of certain kinds from here, and, from a commercial point of view alone, our interests are mutual. Moreover, the advancement of these regions does good to the whole coast, in which we are all interested.

Persons who can contribute information of special or general interest to our readers for these various issues are solicited to send the same as early as possible. If miners will send us descriptions of their mines or camps we shall be very glad to receive them.

As we make this extra effort to advance the interests of all concerned in the places named, we ask that all who can, to favor our enterprise by making the matters more widely known, and the MINING AND SCIENTIFIC PRESS more extensively patronized. The mining literature of the world is comparatively limited. Miners and scientific men especially should be liberal to assist their helpers in a line of publication, which, at best, cannot be expected to be largely profitable while doing strict justice to the highest interests it represents.

The dates of issue of the proposed extra sheets may be varied, if circumstances should demand it, but due notice will be given.

DEMAND it, and take no other iron preparation except BROWN'S IRON BITTERS. It is the best.

California Inventors

Should consult DEWEY & CO., AMERICAN AND FOREIGN PATENT SOLICITORS, for obtaining Patents and Caveats. Established in 1860. Their long experience as journalists and large practice as patent attorneys enables them to offer Pacific Coast inventors far better service than they can obtain elsewhere. Send for free circulars of information. Office of the MINING AND SCIENTIFIC PRESS and PACIFIC RURAL PRESS, No. 252 Market St., S. F. Elevator, 12 Front St.

This paper is printed with Ink Manufactured by Charles Ene Johnson & Co., 509 South 10th St., Philadelphia. Branch Offices—47 Rose St., New York, and 40 La Salle St., Chicago. Agent for the Pacific Coast—Joseph B. Dorety, 439 Commercial St., S. F.

STRONG FACTS!

A great many people are asking what particular troubles BROWN'S IRON BITTERS is good for.

It will cure Heart Disease, Paralysis, Dropsy, Kidney Disease, Consumption, Dyspepsia, Rheumatism, Neuralgia, and all similar diseases.

Its wonderful curative power is simply because it purifies and enriches the blood, thus beginning at the foundation, and by building up the system, drives out all disease.

A Lady Cured of Rheumatism.

Baltimore, Md., May 7, 1883.
My health was much shattered by Rheumatism when I commenced taking Brown's Iron Bitters, and I scarcely had strength enough to attend to my daily household duties. I am now using the third bottle and I am regaining strength daily, and I cheerfully recommend it to all.
I cannot say too much in praise of it. Mrs. MARY E. BRASHBAK, 173 Prentiss St.

Kidney Disease Cured.

Christiansburg, Va., 1883.
Suffering from kidney disease, from which I could get no relief, I tried Brown's Iron Bitters, which cured me completely. A child of mine, recovering from scarlet fever, had no appetite and did not seem to be able to eat at all. I gave him Iron Bitters with the happiest results.
J. KYLE MONTAGUE.

Heart Disease.

Vine St., Harrisburg, Pa. Dec. 2, 1881.
After trying different physicians and many remedies for palpitation of the heart without receiving any benefit, I was advised to try Brown's Iron Bitters. I have used two bottles and never found anything that gave me so much relief.
Mrs. JENNIE HESS.

For the peculiar troubles to which ladies are subject, BROWN'S IRON BITTERS is invaluable. Try it.

Be sure and get the Genuine.

UNITED STATES

Submarine Monitor COMPANY,

230 Montgomery Street, Room 20, SAN FRANCISCO.

WM. H. MILLIKEN, Engineer.

Plans are on exhibition and stock ready for issue. Any information that is desired can be furnished at this office as above.

DIVIDEND NOTICE.

San Francisco Savings Union

532 California Street, Corner Webb.

For the half year ending with June 30, 1883, a dividend has been declared at the rate of four and thirty-two hundredths (4 32-100) per cent per annum on Term Deposits, and three and sixty-one hundredths (3 60-100) per cent per annum on Ordinary Deposits, free of taxes, payable on and after THURSDAY, 12th July, 1883.
LOVELL WHITE, Cashier.

DIVIDEND NOTICE.

The German Savings and Loan Society.

For the half year ending June 30, 1883, the Board of Directors of the GERMAN SAVINGS AND LOAN SOCIETY has declared a dividend on Term Deposits at the rate of four and thirty-two hundredths (4 32-100) per cent per annum, and on Ordinary Deposits at the rate of three and six-tenths (3 6-10) per cent per annum, free from Federal Taxes, and payable on and after the 21 day of July, 1883. By order, GEO. LETTE, Secretary.

THE PACIFIC RURAL PRESS, a most excellent publication, with the beginning of the new year donned a new and exceedingly neat typographical dress. Its reading columns needed no improvement. —*Alameda Enquirer.*

Mining Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

MINERS' HORSE-WHIM

One horse can easily hoist over 1,000 pounds at a depth of 500 feet. The wheel is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The standard of the whim is bolted to bed-timbers, thus avoiding all frame work. When required these whims are made in sections to pack on mules.

BLAKE STEAM PUMP.
More Than 16,000 in Use.

\$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR, —OR— VANNING MACHINE.

Over 400 are now in use, giving entire satisfaction. Saves from 40 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal.

A machine can be seen in working order, and ready to make tests, at the office of Hinckley, Spiers & Hayes, 230 Fremont Street.

To those intending to manufacture or purchase the so-called "Triumph" Concentrator, we have to state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That the patent laws make makers of infringements responsible as well as makers, and the public is therefore warned that there is considerable risk in purchasing any end-shake machine until our various patents have been decided.

That if there are those who for any reason prefer an end-shake machine, we can manufacture and sell to such a machine of that description, as efficient as the Triumph, and at a lower price, and no liability for infringement will then be incurred by the purchaser.

That we shall protect ourselves against any one making, selling or using any machine infringing any of our patents. Patented July 9, 1867; May 4, 1869; Dec. 23, 1874; Sept. 2, 1879; April 27, 1880. Patents applied for.

That we are, and have been, ready at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Company,

Room 7, 108 California Street,
Nov. 6, 1882.

SAN FRANCISCO, CAL.

JAS. LEFFEL'S TURBINE WATER WHEEL, The "Old Reliable,"

MOST PERFECT TURBINE NOW IN USE,

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for New Prices, before buying elsewhere. Now Shops and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO.,

Springfield, Ohio, and 110 Liberty Street, New York City

PARKE & LACY, General Agents, 21 & 23 Fremont St., S. F.

EXCELSIOR BLASTING POWDER.

Manufactured by the

EXCELSIOR POWDER COMPANY.

This is no new, patent, non-explosive Safety Powder, but the Genuine Standard Nitro Glycerine Powder, as safe to use and handle as any other Nitro-Glycerine Powder manufactured. The fumes and gases, common in Nitro-glycerine powders, are destroyed, and do not leave the miner with headache or nausea.

The powder is put up in cartridges of any size to suit the consumer and is exploded in the same manner as all other high explosives; that is, by means of cap and fuse, or by electricity. It is not claimed for this powder that it is a non-explosive, or safer than other Nitro-glycerine powder. All powder, and especially Nitro-glycerine powder, should be handled carefully. The EXCELSIOR POWDER is as safe, and for strength far surpasses any other powder on the market. Address all orders to

EXCELSIOR POWDER COMPANY,

Room 9, No. 3 California St., San Francisco, Cal.

From January to June, 1883
